BULLETIN OF THE ASTRONOMICAL INSTITUTES OF THE NETHERLANDS

1940 May 18

Volume IX

No. 329

COMMUNICATION FROM THE OBSERVATORY AT LEIDEN

Mean colour equivalents of 834 bright stars, compiled by *Ejnar Hertzsprung*.

Since the publication in 1922 of "Mean colour equivalents and hypothetical angular semi-diameters of 734 stars brighter than the fifth magnitude and within 95° of the north pole" ¹⁾ so many series of accurate colour equivalents have appeared, that it seems desirable to include this new material, which increases the weight several times. Furthermore the extended photoelectric series by BOTTLINGER, BECKER and JOHN S. HALL make it possible to correct both the mean values contained in *Leiden Annals* XIV and the colour indices given in *B.A.N.* No. 35 for magnitude equation, of which the photoelectric colour equivalents are supposed to be practically free.

The new and improved scale of quasi c_2/T values, which has been adopted here and is designated by c_2/T' , is similar to that of *Leiden Ann.* XIV. It has been adjusted in such a way that a linear relation to the colour indices of *B.A.N.* No. 35 is obtained. Furthermore the new scale has been freed of the magnitude equation, with which the c_2/T values of *Leiden Ann.* XIV are afflicted and which manifested itself mainly by exaggerated whiteness of the fainter white stars (l.c. pag. 14).

The corrections applied to the c_2/T values of *B.A.N.* No. 35 are as follows:

a. for magnitude: $c_2/T' = c_2/T - 0.078(m-4) \pm 0.012$ (m.e.)

b. for declination:

δ	2°	6°	10°	14°	19°	24°	28°	33°	39°	45°	53°	62°	78°
corr.	7	6	5	4	3	2	1	0	-1	-2	-3	-4	

in units of 0.01 in c_2/T . The mean values from which this table has been derived by comparison with the photoelectric measures are:

$$\delta = \begin{matrix} 13^\circ & 28^\circ & 44^\circ & 62^\circ \end{matrix}$$

$$\Delta \frac{c_2}{T} = +0.049 + 0.013 - 0.009 - 0.035$$

where $c_2/T' = c_2/T + \Delta c_2/T$. The mean value of $\Delta c_2/T$ for all the stars is zero.

c. for right ascension:

It is natural to let the co-efficient of the term $\sin(\alpha - \alpha_0)$ vary with $\cos \delta$. The formula then is correction = $A \sin \alpha \cos \delta + B \cos \alpha \cos \delta$.

The values of $\sin \alpha \cos \delta$ and $\cos \alpha \cos \delta$ can be read off as rectangular co-ordinates if the polar co-ordinates α and $\cos \delta$ are drawn on paper ruled both ways. This reading has been done in the present case for each star. The result of the least squares solution is:

$$\Delta \frac{c_2}{T} = +0.010 - 0.064 \sin \alpha \cos \delta - 0.093 \cos \alpha \cos \delta \pm 0.023 \pm 0.023 \text{ (m.e.)}$$

The co-efficient of $\sin(\alpha - \alpha_0)$ is therefore 0.113/0.023 or nearly 5 times its mean error.

The lines of equal correction on the diagram just described are thus straight and equidistant.

I do not expect that all the systematic errors of the c_2/T values given in *B.A.N.* No. 35 have been eliminated in this way, but only that some improvement has been achieved.

The correction for magnitude equation of the old mean values of c_2/T contained in *Leiden Ann.* XIV was effectuated in two steps. The one step was to apply a general correction for magnitude to c_2/T of all stars, viz. $-0.0683(m-3.778)$ and the other to increase the c_2/T values for the faint white stars. This latter correction was after some trial adopted to be:

$$\Delta c_2/T = +0.146 \pm 0.094 m - 0.23 c_2/T \pm 0.007 \pm 0.014 \pm 0.03 \text{ (m.e.)}$$

This correction was only applied in case $\Delta c_2/T > 0$, thus if $m = 5$ in case $c_2/T < 2.65$ only.

Even after correction for magnitude these c_2/T values seemed to require a reduction of the weight as given in *Leiden Ann.* XIV. For further use these weights were therefore multiplied by 0.7.

The colour equivalents determined photoelectrically by BOTTLINGER and BECKER ¹⁾ were provisionally reduced to the c_2/T' scale by the aid of the formula:

$$c_2/T' \text{ prov.} = 2.052 + 3.011 \times c \text{ BECKER (68)}$$

It then proved that the relation between BECKER's c

¹⁾ *Leiden Ann.* XIV, part 1.

¹⁾ *Veroeffentl. der Univ. Sternwarte Berlin-Babelsberg* 10, part 3, 25.

and c_2/T' was not quite linear and the following additional reductions to the c_2/T' scale were applied:

$$c_2/T' \text{ prov. } \begin{matrix} 1.32 & 1.50 & 1.65 & 1.82 & 2.03 & 2.10 & 2.20 & 2.28 \\ c_2/T' - c_2/T' \text{ prov} & +.06 & +.08 & +.10 & +.12 & +.15 & +.16 & +.18 & +.19 \\ & 2.44 & 2.51 & 2.60 & 2.68 & 2.78 & 2.89 & 3.14 & 3.68 & 4.20 \\ & +.19 & +.18 & +.16 & +.14 & +.12 & +.11 & +.10 & +.08 & +.06 \end{matrix}$$

JOHN S. HALL ¹⁾ determined colour indices at long wavelengths using a caesium cell and two different filters designated by 87 and 89. The readings made with these two filters were compared with that observed without a filter. The two colour indices thus obtained are therefore not independent of each other and the question arises how to combine them. If the proportion between the two colour indices is n , the reading without filter in both cases being taken as zero point, their relative weight is as $2n-1$ to $2n^{-1}-1$.

On page 157 (l.c.) HALL states that the colours 89 have a range of .9 magn. and the colours 87 of 1.6 magn. and on page 175 it is said that "It is interesting to note that the colours of each set are determined with very nearly the same accuracy".

Their relative weights are thus found to be as 20 to 1. That is to say that the addition of the colours 89 to those of 87 increases the weight by 5 percent only. However, a closer examination of the case leads to a different result. For the relation between the two colours 89 and 87 and the c_2/T' values of *Leiden Ann. XIV I* find, disregarding stars of spectral class K2 and yellow:

$$\text{colour 89} = - .649 + 1.294 \log \frac{c_2}{T'}$$

$$\text{colour 87} = - 1.661 + 1.661 \log \frac{c_2}{T'}$$

This gives a scale proportion of 1.28. Then four readings were made without filter and also with filter 89 but only three with filter 87. The proportion between the weights of the colours 87 and 89 then comes out to be 1.9. Instead of 1.9 I have adopted 2, which is practically the same.

Finally the following reductions to the c_2/T' scale of the c_2/T' values calculated by the aid of the above formulae were applied:

$$c_2/T' \begin{matrix} 1.32 & 1.56 & 1.70 & 1.92 & 2.08 & 2.30 & 2.60 \\ c_2/T' - c_2/T' & +.16 & +.13 & +.11 & +.08 & +.06 & +.03 & .00 \\ & 2.77 & 3.27 & 3.49 & 3.76 & 3.98 & 4.20 & 4.33 \\ & -.01 & -.01 & .00 & +.02 & +.04 & +.06 & +.07 \end{matrix}$$

The colour indices of G-stars later published by JOHN S. HALL ²⁾ are related to the c_2/T' scale by the formula: $c_2/T' = 3.100 + 4.154 \times c$ HALL (158).

The photoelectric colour indices determined by

1) *Ap. J.* 79, 164.

2) *Ap. J.* 88, 340.

STEBBINS and HUFFER ¹⁾ and by ELVEY ²⁾ deal merely with white stars. The formulae adopted are:

$$c_2/T' = 1.920 + 2.676 \times c \text{ STEBBINS and HUFFER (174)} \\ \pm .008 \pm .024 \text{ (m.c.)}$$

and

$$c_2/T' = 2.1895 + 1.0460 \times c \text{ ELVEY (131)}$$

The spectral photometric series which have been printed in detail are those of H. JENSEN ³⁾, KIENLE and his collaborators ⁴⁾ and STORER ⁵⁾.

With the exception of the Göttingen ϕ'_T series I have treated all these in practically the same way. For each star the gradient b , corresponding to the formula

$c_2/T' = 1.706 + 26.61(b + 0.344)$, JENSEN, range of wavelength $.4004$ to $.6080 \mu$. (98)

$c_2/T' = 1.677 + 25.47 \times b$, KIENLE S-series, range of wavelength $.4023$ to $.6293 \mu$. (132)

$c_2/T' = 2.275 + 30.69b - 86b^2$, STORER, range of wavelength $.4004$ to $.6120 \mu$. (267)

For the φ_T' values of KIENLE (l.c. Table 17, page 271) the relation $c_2/T' = 1.666 + .656\varphi_T'$ was found and this formula has been used for the reduction of φ_T' to c_2/T' . (254)

Individual values for the stars investigated by JENSEN at KIEL and by KIENLE at Göttingen are given in Table 1, while a similar list of STORER's results obtained at the Lick Observatory is contained in Table 2.

The results of other spectral photometries have only been given in the form of gradients.

The gradients G derived at Greenwich¹⁾ are reduced to the c_2/T' -scale by the aid of the formula

$$c_2/T' = 1.6 + .96G \quad (126)$$

This formula was derived from stars, practically free from reddening by selective extinction in space.

For the gradients g derived at Edinburgh by SAMPSON²⁾ I find: $c_2/T' = 2.668 + .918g$ (118).

The gradation φ_1 determined at the Jungfrauoch by ARNULF, BARBIER, CHALONGE et Mille CARNAVAGGIA³⁾ (l.c. Table XI, p. 172) in the visual part of the spectrum is reduced to the scale of c_2/T' by the aid of the formula $c_2/T' = .3335 + .9782\varphi_1$ (36), the later independent values given in *Annales d'Astrophysique* I, 306, Table VI by the formula $c_2/T' = .6756 + .8452\varphi_1$ (103), and l.c. II, 482, Table II by the formula $c_2/T' = .8618 + .7827\varphi_1$ (100).

The gradient c indicated by Yü⁴⁾ is connected with c_2/T' by the relation $c_2/T' = 2.149 - .370c$ (50).

Other formulae for the reduction of various colour equivalents to the c_2/T' -scale are:

$$c_2/T' = 1.5268 + 1.2604c, \text{ COLLMANN (blue-red)}^5) \quad (44)$$

$$c_2/T' = 1.5339 - .4677c, \text{ GERASIMOVITCH}^6) \quad (143)$$

$$c_2/T' = .3438 + .8596c, \text{ MISS WILLIAMS}^7) \quad (50)$$

$$c_2/T' = 2.625 + 1.673c, \text{ NÖBEL}^8) \quad (55, 25)$$

$$c_2/T' = 1.033 + .1c + .133c^2, \text{ THÜRING}^9) \quad (88 \text{ to } 0)$$

9) *Astron. Nachr.* 269, 298. The whitest stars have been given the weight 88, decreasing to 80, 40 and 10 for $c_2/T' = 2, 3$ and 4 respectively.

Some of the colour equivalents used depend partly on the same visual magnitudes and are therefore not strictly independent of each other, but these correlations are so weak that they may practically be considered as harmless.

There are several determinations of colour equivalents, which have not been taken into account in the present note mainly because of their small weight and the difficulty to determine their systematic errors.

Another compilation of all the available material has been made by BORIS W. KUKARKIN ¹⁾. His general catalogue contains 1207 stars. The formula for the reduction of the mean c_2/T values of KUKARKIN, K , to the scale of c_2/T' is found to be:

$$\frac{c_2}{T'} = 1.0715 + .7117 K + .0356 K^2$$

The weight, i.e. the reciprocal square of the mean error, which has been assigned to the different colour equivalents converted to the c_2/T' scale is added in parentheses behind each formula for the relation between colour equivalent and c_2/T' .

This weight is no exact measure of the accuracy of the colour equivalents used, as the character of the quantity measured by the different observers varies considerably from case to case and may be only approximately related to the adopted scale of c_2/T' . In some cases the colour equivalent measured depends predominantly on the shorter wavelengths, where the absorption of the Balmer series seriously disturbs the "normal" spectral distribution of energy. It should also be remembered that a few of the results included in the present note have been made for special purposes, in which case the colour equivalents are merely to be considered as a byproduct.

In the new General Catalogue given in the present paper all stars contained in *Leiden Annals XIV* have been included with the exception of ζ Aur and β Cyg, in which cases the colour of the integrated light means too little. Other similar cases are e.g. ϵ Boo, δ Sge and 95 Her. In addition about one hundred fainter stars with well determined colour have been included. Fifteen other stars not repeated in the General Catalogue are to be found in Table 2, where they have been marked with an asterisk. The sum of the weights of these 15 stars is $15 \times 267 = 4005$, which added to the weight of the General Catalogue (331965) gives a total of 335970. Further particulars about the duplicity of individual objects are to be found in the *Yale Catalogue of Bright Stars*.

In the great majority of double stars the fainter component belongs to the main series. In case the brighter component also does so its colour determines

with good approximation the colour of the companion, if the difference in magnitude between the two components, Δm , is known. It is then easy to indicate the difference in colour to be expected between the total light of the double star and that of the brighter component alone. Evidently this difference is zero both for $\Delta m = 0$ and for $\Delta m = \infty$. If e.g. the brighter component is like our sun the difference $\Delta c_2/T'$ mentioned has a maximum of .055 at about $\Delta m = 1.5$. The character of the relation between Δm and $\Delta c_2/T'$ is shown in Figure 1.

FIGURE 1.

It is well known that only the white stars radiate with fair approximation like black bodies outside the hydrogen absorption. Concerning the yellow stars the approximation is unsatisfactory as a different effective temperature is derived for different parts of the spectrum.

An empirical and somewhat better representation of the relative distribution of energy in the visible part of star spectra is obtained by the use of λ^{-4} instead of λ^{-2} as argument, but the values of O-C left in doing so still show a systematic character.

Another way to arrive at a fixed scale of colour equivalents, which practically fits ordinary stars, would be to abandon all formulae and to establish a series of standard star spectra (each of which may as well represent the mean of several stars as that of individual objects) and for each star to indicate its place in that series. For this purpose the spectrum of the star in question should be compared with three standard spectra and the sum of the squares of the deviations from each of the standard spectra computed. These three sums determine the place of the star in question in the adopted series. An example will illustrate this procedure.

In STORER's paper (l.c. Table IV) individual values of Δm_λ are given for each star investigated. Out of this table I have prepared three fictive standard stars A, B and C. They are respectively represented by the mean values of Δm_λ for H.R. 6556 and 114, H.R. 8131 and 544 and H.R. 8650 and 7602. For convenience the sum of the used values of Δm_λ has been made zero for each star. The procedure just described is shown by Table 3.

comparison star S_c	adopted scale	$\Sigma(S-S_c)^2$	Δ	$\Delta_1 + \Delta_2$	$\Delta_1 - \Delta_2$
A	2.0	^m .6562	^m .5672	^m .1170	^m .10174
B	2.5	.0890	— .4502		
C	3.0	.5392			
S	2.53	.0575			

The result is that the scale value of the star S (H.R. 5868) taken as an example is

$$2.5 + \frac{1}{2} \cdot \frac{.1170}{.10174} \times .5 = 2.53$$

It is of special interest to compare these accurate colours with the absolute magnitudes of stars, as far as they are well known. This has been done in Table 4¹⁾ and in Figure 2. It is readily seen that a smooth curve can be drawn which represents the

FIGURE 2.

Abscissa: $m + 5 \log p$, Ordinate: $\frac{c_2}{T'}$

main series in such a way that practically no star in the present list deviates more to the white side of that curve than may be explained by observational errors. The main series is well represented by the formula

$$\frac{c_2}{T'} = 2.7 \times 1.105^{m + 5 \log p}$$

¹⁾ The absolute magnitudes of stars belonging to the UMa group have been taken from W. M. SMART'S paper in *Monthly Notices* 99, 448.

as far as the stars of Table 4 go, but the formula is not recommended for extrapolation outside the interval $-5.3 < m + 5 \log p < 3.6$, though it gives $c_2/T' = 0$ for $m + 5 \log p = -\infty$. There are indications that the reddening of the colour for $m + 5 \log p > +4$ does not go on at the rate required by the formula. In fact the effective wavelengths of such absolutely faint stars do not show any further increase with decreasing brightness (*Ap. J.* 42, 349; 1915).

The new Greenwich gradients published in *M. N.* 100, 190 just came in time to be included in the present paper. It is now evident that stars affected by selective extinction of light in space do not fit into the normal sequence of colours as the place assigned to such stars in that sequence is shifted towards the red with increasing wavelength of the light used. The distribution of energy in the spectra of these stars is therefore not, as in the case of ordinary stars, properly indicated by a single figure.

¹⁾ each of two equal components.

²⁾ β Aur may not be a member of the UMa group.

³⁾ mean of 4 yellow Hyades.

⁴⁾ mean of 10 white Hyades.

⁵⁾ weight of c_2/T' relatively small ($1/(m.e.)^2 = 68$).
