(Received 7 March 2011; published 26 April 2011)

The bulk microwave conductivity of a dirty d -wave superconductor is known to depend sensitively on the range of the disorder potential: long-range scattering enhances the conductivity, whereas short-range scattering has no effect. Here we show that the three-terminal electrical conductance of a normal-metal- d -wave superconductor-normal-metal junction has a dual behavior: short-range scattering suppresses the conductance, whereas long-range scattering has no effect.

I. INTRODUCTION

As pointed out by Lee in an influential paper,¹ disorder has two competing effects on the microwave conductivity of a layered superconductor with d -wave symmetry of the pair potential. On the one hand, disorder increases the density of low-energy quasiparticle excitations, located in the Brillouin zone near the intersection of the Fermi surface with the nodal lines of vanishing excitation gap. On the other hand, disorder reduces the mobility of these nodal fermions. For short-range scattering the two effects cancel,² producing a disorder-independent microwave conductivity $\sigma_0 \simeq (e^2/h)k_F\xi_0$ per layer in the low-temperature, low-frequency limit (with ξ_0 the coherence length and k_F the Fermi wave vector). For long-range scattering the first of the two effects wins,^{3,4} which explains the conductivity enhancement measured in the high- T_c cuprates^{5,6} (where long-range scattering dominates⁷).

The microwave conductivity is a bulk property of an unbounded system, of length L and width W large compared to the mean free path l . A finite system makes it possible to study the crossover from diffusive to ballistic transport, as L and W become smaller than l . We have recently shown⁸ that the transmission of nodal fermions over a length L in the range $\xi_0 \ll L \ll l$, W is pseudodiffusive: The transmission probability has the W/L scaling of a diffusive system, even in the absence of any disorder. The corresponding conductance G_0 is close to the value $(W/L)\sigma_0$, which one would expect from the microwave conductivity, to a small correction of order $(k_F\xi_0)^{-2} \ll 1$.

It is the purpose of this paper to investigate the effects of disorder on the pseudodiffusive conductance, as L becomes larger than l . We find a qualitatively different behavior than for the microwave conductivity, with an exponentially suppressed conductance in the case of short-range scattering and an unaffected conductance $G \simeq G_0$ for long-range scattering.

II. FORMULATION OF THE PROBLEM

The geometry to measure the transmission of nodal fermions is illustrated in Fig. 1. It consists of a superconducting strip S between two normal metal contacts N_1 and N_2 . The transverse width W of the superconductor is assumed to be large compared to the separation L of the NS interfaces to avoid edge effects. Contact N_1 is at an elevated voltage V , while S and N_2 are both grounded. The current I_2 through contact

N_2 measures the transmitted charge, which is carried entirely by nodal fermions if $L \gg \xi_0$. The nodal lines are the x and y axes, oriented at an angle α relative to the normal to the NS interfaces. There are four nodal points, A , B , C , and D , in the Brillouin zone, at the intersection of the nodal lines and the Fermi surface. The nodal fermions have an anisotropic dispersion relation, with a velocity v_F parallel to the nodal axis and a much smaller velocity $v_\Delta = v_F/k_F\xi_0$ perpendicular to the nodal axis.

The (three-terminal) conductance $G = I_2/V$ was calculated in Ref. 8 in the clean limit $L \ll l$, with the result (per layer)

$$G_{\text{clean}} = \frac{2e^2}{h} \frac{W}{L} \frac{v_F^2 + v_\Delta^2}{\pi v_F v_\Delta} \frac{\Gamma_1 \Gamma_2}{(2 - \Gamma_1)(2 - \Gamma_2)}, \quad (2.1)$$

independent of α . The factors $\Gamma_1, \Gamma_2 \in (0, 1)$ are the (mode-independent) transmission probabilities of tunnel barriers at the N_1S and N_2S interfaces. We have assumed that the tunnel barriers do not couple the nodes, which requires $\alpha \gg \xi_0/L$ and $\pi/4 - \alpha \gg \xi_0/L$. Since $\xi_0/L \ll 1$, this is the generic case.

We now wish to move away from the clean limit and include scattering by electrostatic potential fluctuations. We distinguish two regimes, depending on the magnitude of the correlation length l_c of the potential fluctuations. In the regime $k_F l_c \gg 1$ of long-range disorder, the nodes remain uncoupled and can be treated separately. We consider this regime of *intranode* scattering first and then include the effects of *internode* scattering when l_c becomes smaller than $1/k_F$.

III. INTRANODE SCATTERING REGIME

In the absence of internode scattering, the electron and hole components of the wave function $\Psi = (\Psi_e, \Psi_h)$ of nodal fermions (at excitation energy ε) are governed by the anisotropic Dirac equation $H\Psi = \varepsilon\Psi$. Near node A the Hamiltonian takes the form⁹

$$H = -i\hbar(v_F\sigma_z\partial_x + v_\Delta\sigma_x\partial_y) + V_\mu\sigma_z + V_\Delta\sigma_x. \quad (3.1)$$

The two terms $V_\mu(x, y)$ and $V_\Delta(x, y)$ describe, respectively, long-range disorder in the electrostatic potential and in the s -wave component of the pair potential. These two types of disorder preserve time-reversal symmetry. The Hamiltonian anticommutes with the Pauli matrix σ_y , belonging to the chiral symmetry class AIII of Ref. 9.

FIG. 1. (Color online) Geometry to measure the transmission of quasiparticles at the nodes (red circles) of the pair potential with d_{xy} symmetry.

Following Refs. 10 and 11, at zero energy, the disorder potentials can be transformed out from the Dirac equation by means of the transformation $\Psi \mapsto \exp(i\phi + \chi\sigma_y)\Psi_0$, with fields ϕ and χ determined by

$$v_F \partial_x \phi + v_\Delta \partial_y \chi = -V_\mu / \hbar, \quad (3.2a)$$

$$v_F \partial_x \chi - v_\Delta \partial_y \phi = V_\Delta / \hbar. \quad (3.2b)$$

If $H\Psi = 0$ then also $H_0\Psi_0 = 0$, where H_0 is the Dirac Hamiltonian without disorder ($V_\mu \equiv 0$ and $V_\Delta \equiv 0$).

The transformation from Ψ to Ψ_0 leaves the particle current density unaffected but not the electrical current density: The particle current density \mathbf{j} reads

$$(j_x, j_y) = \Psi^\dagger (v_F \sigma_z, v_\Delta \sigma_x) \Psi = \Psi_0^\dagger (v_F \sigma_z, v_\Delta \sigma_x) \Psi_0, \quad (3.3)$$

whereas for the electrical current density \mathbf{i} one has

$$i_y = 0, \quad i_x = e v_F \Psi^\dagger \Psi = e v_F \Psi_0^\dagger \exp(2\chi\sigma_y) \Psi_0. \quad (3.4)$$

This is consistent with the findings of Durst and Lee,³ whereby the low-energy effects of intranode scattering on the density of states and on the mobility cancel for the thermal conductivity (proportional to the particle current) but not for the electrical conductivity (which is increased by disorder).

As we now show, for the conductance of a finite system, the effect of intranode scattering differs entirely. Following Ref. 8, the conductance is determined by the transfer matrix \mathcal{M} relating right-moving and left-moving states $\Phi_1 = (\Phi_1^+, \Phi_1^-)$ in N_1 to right-moving and left-moving states $\Phi_2 = (\Phi_2^+, \Phi_2^-)$ in N_2 . It is convenient to rotate the coordinate system from x and y along the nodal axes to coordinates s and t perpendicular and parallel to the NS interfaces. The transfer matrix is defined by

$$\Phi_2(L, t) = \int dt' \mathcal{M}(t, t') \Phi_1(0, t'). \quad (3.5)$$

For wave vectors in the normal metal coupled to node A , the right-movers are electrons Φ_e^+ and the left-movers are holes Φ_h^- , so an electron incident from contact N_1 can be

transmitted into contact N_2 only as an electron, not as a hole. The corresponding transmission matrix t_{ee} is determined by the transfer matrix via

$$t_{ee} = (\mathcal{M}_{11}^\dagger)^{-1}, \quad \mathcal{M} = \begin{pmatrix} \mathcal{M}_{11} & \mathcal{M}_{12} \\ \mathcal{M}_{21} & \mathcal{M}_{22} \end{pmatrix}. \quad (3.6)$$

The contribution G_A to the electrical conductance from node A then follows from

$$G_A = \frac{2e^2}{h} \text{Tr} t_{ee} t_{ee}^\dagger, \quad (3.7)$$

with a factor of 2 to account for both spin directions. The full conductance contains an additional contribution from node B , determined by similar expressions with α replaced by $\alpha - \pi/2$.

The Hamiltonian (3.1) does not apply within a coherence length ξ_0 from the NS interfaces, where the depletion of the pair potential should be taken into account. We assume weak disorder, $l \gg \xi_0$, so we can use the clean-limit results of Ref. 8 in this interface region. For simplicity, we do not include tunnel barriers at this stage ($\Gamma_1 = \Gamma_2 = 1$). The transfer matrix through the superconductor is then given by

$$\mathcal{M} = \exp(i\phi_R + \sigma_y \chi_R) \exp(-iL v_F v_\Delta v_\alpha^{-2} \sigma_y \partial_t + L \varphi_\alpha \partial_t) \times \exp(-i\phi_L - \sigma_y \chi_L), \quad (3.8)$$

with the abbreviations

$$v_\alpha = \sqrt{v_F^2 \cos^2 \alpha + v_\Delta^2 \sin^2 \alpha}, \quad (3.9)$$

$$\varphi_\alpha = \frac{1}{2} v_\alpha^{-2} (v_F^2 - v_\Delta^2) \sin 2\alpha. \quad (3.10)$$

The fields $\phi_L(t), \chi_L(t)$ are evaluated at the left NS interface ($s = 0$) and the fields $\phi_R(t), \chi_R(t)$ are evaluated at the right NS interface ($s = L$).

We now follow Ref. 10 and use the freedom to impose boundary conditions on the solution of Eq. (3.2). Demanding $\chi = 0$ on the NS interfaces fixes both χ and ϕ (up to an additive constant). The transfer matrix (3.8) then depends only on the disorder through the terms $\exp(i\phi_R)$ and $\exp(-i\phi_L)$, which are unitary transformations and therefore drop out of the conductance (3.7). We conclude that the electrical conductance (2.1) is not affected by long-range disorder.

Tunnel barriers affect the conductance in two distinct ways. First, at both NS interfaces, we need to consider all four states $\Phi_{e,h}^\pm$ that have the same component of the wave vector parallel to the NS interface (Φ_e^+, Φ_h^- have the opposite perpendicular component than Φ_e^-, Φ_h^+). However, only one right-moving and one left-moving superposition of these modes, Φ_n^\pm , is coupled by the transfer matrix to the other side of the system:

$$\Phi_n^+ = (2 - \Gamma_n)^{-1/2} [\Phi_e^+ + (1 - \Gamma_n)^{1/2} \Phi_h^+], \quad (3.11a)$$

$$\Phi_n^- = (2 - \Gamma_n)^{-1/2} [(1 - \Gamma_n)^{1/2} \Phi_e^- + \Phi_h^-]. \quad (3.11b)$$

The superposition of incoming electron and hole states orthogonal to Φ_n^+ is fully reflected by the tunnel barrier and the superconductor and so plays no role in the conductance. For a detailed derivation of these formulas see Appendix A.

Second, the modes Φ_n^\pm are only partially transmitted through the barriers. We have calculated the transmission

probability (see Appendix A for details), and found that it can be accounted for by the following transformation of the transfer matrix,

$$\mathcal{M} \mapsto e^{\gamma_2 \sigma_y} \mathcal{M} e^{\gamma_1 \sigma_y}, \quad \gamma_n = \frac{1}{2} \ln(2/\Gamma_n - 1). \quad (3.12)$$

With tunnel barriers, the transmission matrix contains mixed electron and hole elements,

$$\mathcal{T} = \begin{pmatrix} t_{ee} & t_{eh} \\ t_{he} & t_{hh} \end{pmatrix} = U_2^\dagger \begin{bmatrix} (\mathcal{M}_{11}^\dagger)^{-1} & 0 \\ 0 & 0 \end{bmatrix} U_1, \quad (3.13)$$

where the unitary matrices U_n transform from the electron-hole basis to the basis state Φ_n^+ and its (fully reflected) orthogonal complement,

$$U_n = (2 - \Gamma_n)^{-1/2} \begin{bmatrix} 1 & (1 - \Gamma_n)^{1/2} \\ (1 - \Gamma_n)^{1/2} & -1 \end{bmatrix}. \quad (3.14)$$

Finally, the contribution G_A to the electrical conductance from node A follows from

$$G_A = \frac{2e^2}{h} \text{Tr}(t_{ee} t_{ee}^\dagger - t_{he} t_{he}^\dagger). \quad (3.15)$$

With tunnel barriers, not just nodes A and B but also nodes C and D contribute to the full conductance.

Collecting results, we substitute Eq. (3.8) (with χ_L and χ_R both fixed at zero) into Eq. (3.12) to obtain the transfer matrix, and then substitute the 1,1 block into Eq. (3.13) for the transmission matrix. Disorder only enters through the factors $\exp(i\phi_R)$ and $\exp(-i\phi_L)$, which mix the modes on the superconducting side of the tunnel barriers. Since the tunnel probabilities are assumed to be mode independent, these factors commute with the U_n 's and cancel on taking the trace in Eq. (3.15). We thus recover the clean-limit result (2.1), independent of any disorder potential. Disorder would have an effect on the conductance for mode-dependent tunnel probabilities, but since the modes in the normal metal couple to a narrow range of transverse wave vectors in the superconductor, the assumption of mode independence is well justified.

As an aside we mention that the thermal (rather than electrical) conductance $G_{\text{thermal}} \propto \text{Tr} \mathcal{T} \mathcal{T}^\dagger$ would be independent of disorder also for the case of mode-dependent tunnel probabilities, since the U_n 's drop out of the trace. The tunnel barriers would then still enter in the transfer matrix through the terms $e^{\gamma_n \sigma_y}$ in Eq. (3.12), but these terms have the same effect as δ function contributions to V_μ and can therefore be removed by including them in Eq. (3.2). The conclusion is that the thermal conductance is independent of both disorder and tunnel barriers, while the electrical conductance is independent of disorder but dependent on tunnel barriers through the factors $\Gamma_n/(2 - \Gamma_n)$. Note that the Wiedemann-Franz relation between thermal and electrical conductance does not apply.

IV. EFFECT OF INTERNODE SCATTERING

So far we have considered only intranode scattering. For short-range disorder we have to include also the effects of internode scattering. Internode scattering suppresses the electrical conductance, measured between the normal metals N_1 and N_2 , because an electron injected from N_1 into nodes A

or B and then scattered to nodes C or D will exit into N_2 as a hole of opposite electrical charge. (The charge deficit is drained to ground via the superconductor.) The thermal conductance, in contrast, remains unaffected by internode scattering because electrons and holes transport the same amount of energy. (Again, the Wiedemann-Franz relation does not apply.) We first give a semiclassical analytical theory and then a fully quantum mechanical numerical treatment.

A. Semiclassical theory

We assume that the mean free path l for intranode scattering is short compared to the internode scattering length. Semiclassically we may then describe the internode scattering by a (stationary) reaction-diffusion equation for the carrier densities n_v ,

$$\nabla \cdot \mathbf{D}_v \cdot \nabla n_v + \sum_{v' \neq v} (\gamma_{vv'} n_{v'} - \gamma_{v'v} n_v) = 0. \quad (4.1)$$

The labels $v, v' \in \{A, B, C, D\}$ indicate the nodes, with diffusion tensor \mathbf{D}_v and scattering rate $\gamma_{vv'}$ from v' to v . For simplicity we assume there is no tunnel barrier at the NS interfaces, and seek a solution $n_v(s)$ with boundary conditions

$$n_v(0) = \frac{1}{2}(\delta_{v,A} + \delta_{v,B}) e V \rho_F, \quad n_v(L) = 0. \quad (4.2)$$

Here ρ_F is the density of states per node at the Fermi energy, and we have chosen the sign of the applied voltage V such that electrons (rather than holes) are injected into the superconductor from N_1 .

The diffusion tensor is diagonal in the x - y basis, with components D_μ and D_Δ in the direction of v_μ and v_Δ , respectively. The average diffusion constant is $\bar{D} = \frac{1}{2}(D_\mu + D_\Delta)$ and we also define $D_\alpha = D_\mu \cos^2 \alpha + D_\Delta \sin^2 \alpha$. We distinguish internode scattering between opposite nodes, with rate γ_1 , and between adjacent nodes, with rate γ_2 . Because the solution $n_v(s)$ in the s - t basis is independent of the transverse coordinate t , we may replace the Laplacian $\nabla \cdot \mathbf{D}_v \cdot \nabla \mapsto D_v d^2/ds^2$ with $D_A = D_C = D_\alpha$ and $D_B = D_D = 2\bar{D} - D_\alpha$.

We seek the current into N_2 , given by

$$I_2 = -eW \lim_{s \rightarrow L} \frac{d}{ds} [D_A n_A + D_B n_B - D_C n_C - D_D n_D]. \quad (4.3)$$

This can be obtained by integrating the reaction-diffusion equation (4.1) in the way explained in Ref. 12. The result is

$$I_2 = e^2 V \rho_F W \frac{1}{2} \left[\frac{\sqrt{2(\gamma_1 + \gamma_2) D_\alpha}}{\sinh \sqrt{2L^2(\gamma_1 + \gamma_2)/D_\alpha}} + \frac{\sqrt{2(\gamma_1 + \gamma_2)(2\bar{D} - D_\alpha)}}{\sinh \sqrt{2L^2(\gamma_1 + \gamma_2)/(2\bar{D} - D_\alpha)}} \right]. \quad (4.4)$$

In the small- L limit (when intervalley scattering can be neglected) we recover an α -independent conductance $I_2/V \rightarrow e^2 \rho_F \bar{D} W/L$, consistent with the expected result (2.1). For large L the conductance decays exponentially $\propto e^{-L/l_{\text{inter}}}$, with

$$l_{\text{inter}} = \sqrt{\frac{1}{2} \min(D_\alpha, 2\bar{D} - D_\alpha)/(\gamma_1 + \gamma_2)} \quad (4.5)$$

the internode scattering length. For weak disorder ($k_F l \gg 1$) this decay length is much shorter than the Anderson localization length $\simeq l e^{k_F l}$, so we are justified in treating the transport semiclassically by a diffusion equation.

B. Fully quantum mechanical solution

The Hamiltonian in the presence of internode scattering belongs to symmetry class CI of Ref. 9, restricted by time-reversal symmetry and electron-hole symmetry—but without the chiral symmetry that exists in the absence of internode scattering.

To write the Hamiltonian \mathcal{H} of the four coupled nodes in a compact form, we use three sets of Pauli matrices: For each $i = x, y, z$ the 2×2 Pauli matrix σ_i couples electrons and holes, γ_i couples opposite nodes (A to C and B to D), and τ_i couples adjacent nodes (A to B and C to D). The requirements of time-reversal symmetry and electron-hole symmetry are given, respectively, by

$$\gamma_x \mathcal{H}^* \gamma_x = \mathcal{H}, \quad (\gamma_x \otimes \sigma_y) \mathcal{H}^* (\gamma_x \otimes \sigma_y) = -\mathcal{H}. \quad (4.6)$$

In the absence of disorder, the Hamiltonian is given by

$$\begin{aligned} \mathcal{H}_{\text{clean}} = & p_x (v_F \tau_+ \otimes \sigma_z + v_\Delta \tau_- \otimes \sigma_x) \otimes \gamma_z \\ & + p_y (v_F \tau_- \otimes \sigma_z + v_\Delta \tau_+ \otimes \sigma_x) \otimes \gamma_z. \end{aligned} \quad (4.7)$$

The momentum operator is $\mathbf{p} = -i\hbar\partial/\partial\mathbf{r}$ and we have defined $\tau_\pm = \frac{1}{2}(\tau_0 \pm \tau_z)$, with τ_0 the 2×2 unit matrix.

Since the effects of disorder in the electrostatic potential $V_\mu(\mathbf{r})$ and in the pair potential $V_\Delta(\mathbf{r})$ are equivalent,⁹ we restrict ourselves to the former. The relevant Fourier components of $V_\mu(\mathbf{r})$ can be represented by the expansion

$$\begin{aligned} V_\mu(\mathbf{r}) = & \mu_0(\mathbf{r}) \\ & + \mu_1(\mathbf{r}) e^{i(\mathbf{k}_C - \mathbf{k}_A) \cdot \mathbf{r}} + \mu_2(\mathbf{r}) e^{i(\mathbf{k}_D - \mathbf{k}_B) \cdot \mathbf{r}} \\ & + \mu_3(\mathbf{r}) e^{i(\mathbf{k}_B - \mathbf{k}_A) \cdot \mathbf{r}} + \mu_4(\mathbf{r}) e^{i(\mathbf{k}_C - \mathbf{k}_B) \cdot \mathbf{r}}, \end{aligned} \quad (4.8)$$

where \mathbf{k}_X is the wave vector of node $X = A, B, C, D$ (see Fig. 1). The Fourier amplitudes $\mu_p(\mathbf{r})$ are all slowly varying functions of \mathbf{r} , with correlation length $\xi \gg 1/k_F$. The amplitude μ_0 is responsible for intranode scattering, arising from spatial Fourier components of $V(\mathbf{r})$ with wave vector $\ll k_F$ (long-range scattering). The other four amplitudes arise from Fourier components with wave vector $\gtrsim k_F$ (short-range scattering). Of these internode scattering potentials, μ_1, μ_2 scatter between opposite nodes and μ_3, μ_4 scatter between adjacent nodes.

The Hamiltonian $\mathcal{H} = \mathcal{H}_{\text{clean}} + \mathcal{H}_{\text{disorder}}$ contains an electrostatic disorder contribution $\mathcal{H}_{\text{disorder}} \propto \sigma_z$. Six combinations of Pauli matrices are allowed by the symmetry (4.6), five of which have independent amplitudes:

$$\mathcal{H}_{\text{disorder}} = \sum_{n=0}^4 \mathcal{H}_n \otimes \sigma_z, \quad \text{with} \quad (4.9)$$

$$\begin{aligned} \mathcal{H}_0 = & \mu_0(\mathbf{r}) [\tau_+ \otimes \gamma_0 + \tau_- \otimes \gamma_0] = \mu_0(\mathbf{r}) \tau_0 \otimes \gamma_0, \\ \mathcal{H}_1 = & \mu_1(\mathbf{r}) \tau_+ \otimes \gamma_x, \quad \mathcal{H}_2 = \mu_2(\mathbf{r}) \tau_- \otimes \gamma_x, \\ \mathcal{H}_3 = & \mu_3(\mathbf{r}) \tau_x \otimes \gamma_0, \quad \mathcal{H}_4 = \mu_4(\mathbf{r}) \tau_x \otimes \gamma_x. \end{aligned} \quad (4.10)$$

We have solved the quantum mechanical scattering problem of the four coupled Dirac Hamiltonians numerically by discretizing \mathcal{H} on a grid. Since the electrostatic potential appears

FIG. 2. (Color online) Differential conductance as a function of sample length, calculated numerically from the four coupled Dirac Hamiltonians of nodal fermions. The solid curves are at zero voltage and the dashed curves at nonzero voltage. If only intranode scattering is present (upper curves), the differential conductance is close to the value G_{clean} from Eq. (2.1). Including also internode scattering (lower curves) causes the conductance to decay strongly below G_{clean} .

in the form of a vector potential in the Dirac Hamiltonian, in our numerical discretization we are faced with a notorious problem from the theory of lattice fermions: How to avoid fermion doubling while preserving gauge invariance.¹³ The transfer matrix discretization method we use, from Ref. 14, satisfies gauge invariance only in the continuum limit. We ensure that we have reached that limit by reducing the mesh size of the grid until the results have converged.

We fixed the width of the d -wave strip at $W = 150\xi$, oriented at an angle $\alpha = \pi/8$ with the nodal lines, and increased L at fixed ξ . We set the anisotropy at $v_F/v_\Delta = 2$ and did not include tunnel barriers for simplicity. All five amplitudes $\mu_p(\mathbf{r})$ are taken as independently fluctuating Gaussian fields, with the same correlation length ξ . The Gaussian fields have zero ensemble average, $\langle \mu_p(\mathbf{r}) \rangle = 0$, and second moment

$$K_p = (\hbar v_F)^{-2} \int d\mathbf{r} \langle \mu_p(0) \mu_p(\mathbf{r}) \rangle. \quad (4.11)$$

We took $K_0 = 1$ and either $K_1 = K_2 = K_3 = K_4 = 0$ (only intranode scattering) or $K_1 = K_2 = K_3 = K_4 = 0.4$ (both intranode and internode scattering). The results in Fig. 2 give the differential conductance dI_2/dV , both at zero voltage and at a voltage of $V = 0.2\hbar v_F/e\xi$.

Without internode scattering, we recover precisely the analytical result $dI_2/dV = G_{\text{clean}}$ at $V = 0$. At nonzero voltages, dI_2/dV rises above G_{clean} with increasing L , consistent with the expectations¹⁰ for the crossover from pseudodiffusive to ballistic conduction at $V \simeq \hbar v_F/eL$. Internode scattering causes dI_2/dV to drop strongly below G_{clean} with increasing L , both at zero and at nonzero voltages. The decay is approximately exponential, consistent with our semiclassical theory (although the range accessible numerically is not large enough to accurately extract a decay rate).

V. CONCLUSION

In summary, we have shown that the effect of disorder on the electrical current transmitted through a normal-metal- d -wave-superconductor-normal metal junction differs strikingly depending on the range of the disorder potential: Long-range scattering has no effect, while short-range scattering suppresses the current exponentially. This behavior is dual to what

FIG. 3. (Color online) Sketch of the normal-superconducting interface, with the plane wave modes taking part in conduction with a fixed energy and transverse momentum. To define the modes $\phi_{e,h}^{+,-}$, a piece of normal metal with length $\rightarrow 0$ is inserted between the tunnel barrier I and the superconductor S.

is known^{3,4} for the bulk conductivity, which is unaffected by short-range scattering and increased by long-range scattering. Because of the exponential sensitivity $\propto e^{-L/l_{\text{inter}}}$, we propose the setup of Fig. 1 as a way to measure the internode scattering length l_{inter} .

As a direction for future research, it would be interesting to study the transmission in the geometry of Fig. 1 of low-energy excitations that are not located near the nodal points of the pair potential. A mechanism for the formation of non-nodal zero-energy states in d -wave superconductors has been studied in Refs. 15 and 16.

APPENDIX: TUNNEL BARRIER AT THE NS INTERFACE

We consider a tunnel barrier between the normal metal contact N_1 and the superconductor. To be specific, we describe the left end of our setup, the derivations for the right contact follow analogously. We introduce an additional normal metal of zero length between the tunnel barrier and the superconductor, as illustrated in Fig. 3. For simplicity, we assume translation invariance along the NS interface holds: then the energy and the wave number along the NS interface are good quantum numbers. The tunnel barrier mixes the four modes with these constants in the normal lead N_1 : $\Phi_{e,h}^{+,-}$ for right-/left-propagating electrons, and $\Phi_{h,e}^{+,-}$ for right-/left-propagating holes, with the four modes with these constants

in N'_1 : $\phi_{e,h}^{+,-}$ and $\phi_{h,e}^{+,-}$. We have

$$\begin{pmatrix} \Phi_e^- \\ \Phi_e^+ \\ \Phi_h^- \\ \Phi_h^+ \end{pmatrix} = \begin{pmatrix} \tau & \tau' & 0 & 0 \\ t & t' & 0 & 0 \\ 0 & 0 & \tau^* & t'^* \\ 0 & 0 & t^* & \tau'^* \end{pmatrix} \begin{pmatrix} \Phi_e^+ \\ \Phi_e^- \\ \Phi_h^+ \\ \Phi_h^- \end{pmatrix}. \quad (\text{A1})$$

Here $t = \sqrt{\Gamma_1} e^{i\chi}$ and $t' = \sqrt{\Gamma_1} e^{i\chi'}$ are the electron transmission amplitudes, $\chi, \chi' \in \mathbb{R}$, and τ and τ' are the electron reflection amplitudes.

Since the angle α between the normal to the NS interface and the nodal line is taken to be generic, $0 \ll \alpha \ll -\pi/4$, the modes ϕ_h^+ and ϕ_e^- cannot propagate in the superconductor. They are localized near the NS interface and follow Andreev reflection: $\phi_e^- = -i\phi_h^+$. Using this, we can write the scattering matrix S representing the combined effect of the tunnel barrier and the Andreev reflections on the propagating modes as

$$\begin{pmatrix} \Phi_e^- \\ \Phi_h^- \\ \Phi_e^+ \\ \Phi_h^+ \end{pmatrix} = S \begin{pmatrix} \Phi_e^+ \\ \Phi_h^+ \\ \Phi_e^- \\ \Phi_h^- \end{pmatrix}; \quad S = \begin{pmatrix} \tau & -t't' & -t'it'^* \\ 0 & \tau' & t'^* \\ t & -\tau'it' & -\tau'it'^* \end{pmatrix}. \quad (\text{A2})$$

Now there are two incoming propagating modes from the left but only one outgoing propagating mode to the right. This implies that there is a superposition of Φ_e^+ and Φ_h^+ that is reflected with unit probability into a superposition of Φ_e^- and Φ_h^- . Orthogonal to these uncoupled superpositions are the *relevant modes* $\Phi_1^+ = u_e \Phi_e^+ + u_h \Phi_h^+$ and $\Phi_1^- = v_e \Phi_e^- + v_h \Phi_h^-$, which are coupled to the propagating modes in the superconductor. We can find them from Eq. (A2) by just observing what S^\dagger and S take $(0,0,1)^\dagger$ to:

$$\begin{pmatrix} u_e \\ u_h \end{pmatrix} = \frac{1}{\mathcal{N}} \begin{pmatrix} e^{-i\chi} \\ i\tau'^* e^{i\chi} \end{pmatrix}; \quad \begin{pmatrix} v_e \\ v_h \end{pmatrix} = \frac{1}{\mathcal{N}} \begin{pmatrix} i\tau'^* e^{i\chi'} \\ e^{-i\chi'} \end{pmatrix}, \quad (\text{A3})$$

where $\mathcal{N} = \sqrt{2 - \Gamma_1}$ is a normalizing factor. For our setup, all phase factors here can be absorbed into the definitions of the plane wave modes in contact N_1 , and we obtain Eqs. (3.11).

Acting with S on $(u_e^*, u_h^*, 0)^\dagger$ allows us to infer the transmission and reflection amplitudes of the relevant modes, from which we can obtain the transfer matrix,

$$\begin{pmatrix} \Phi_e^+ \\ \Phi_h^+ \end{pmatrix} = \mathcal{M}_1 \begin{pmatrix} \Phi_1^+ \\ \Phi_1^- \end{pmatrix}; \quad \mathcal{M}_1 = \frac{1 + (1 - \Gamma_1)\sigma_y}{\sqrt{\Gamma_1(2 - \Gamma_1)}}. \quad (\text{A4})$$

This transfer matrix can be written in a succinct form with a real parameter γ_1 characterizing the tunnel barrier:

$$\mathcal{M}_1 = \exp[\gamma_1 \sigma_y]; \quad \gamma_1 = \frac{1}{2} \ln \frac{2 - \Gamma_1}{\Gamma_1}. \quad (\text{A5})$$

This and the analogous calculation for the right edge of the system lead directly to Eq. (3.12).
