ABSTRACT

Background: Macrophages constitute a heterogeneous cell population with pro- (M Φ 1) and anti-inflammatory (M Φ 2) cells. The soluble chitinase-like-protein YKL-40 is expressed in macrophages and various other cell types, and has been linked to a variety of inflammatory diseases, including COPD. Dexamethasone strongly reduces YKL-40 expression in peripheral blood mononuclear cells (PBMC) *in vitro*. We hypothesized that: a) YKL-40 is differentially expressed by M Φ 1 and M Φ 2, b) is decreased by corticosteroids and c) that long-term treatment with inhaled corticosteroids (ICS) affects YKL-40 levels in serum and sputum of COPD patients.

Methods: Monocytes of healthy subjects were cultured *in vitro* for 7 days with either GM-CSF or M-CSF (for M Φ 1 and M Φ 2, respectively) and stimulated for 24h with LPS, TNF α , or oncostatin M (OSM). M Φ 1 and M Φ 2 differentiation was assessed by measuring secretion of IL-12p40 and IL-10, respectively. YKL-40 expression in macrophages was measured by quantitative RT-PCR (qPCR) and ELISA; serum and sputum YKL-40 levels were analyzed by ELISA.

Results: Pro-inflammatory M Φ 1 cells secreted significantly more YKL-40 than M Φ 2, which was independent of stimulation with LPS, TNF α or OSM ($P < 0.001$) and confirmed by qPCR. Dexamethasone dose-dependently and significantly inhibited YKL-40 protein and mRNA levels in M Φ 1. Serum YKL-40 levels of COPD patients were significantly higher than sputum YKL-40 levels but were not significantly changed by ICS treatment.

Conclusions: YKL-40 secretion from M Φ 1 cells is higher than from M Φ 2 cells and is unaffected by further stimulation with pro-inflammatory agents. Furthermore, YKL-40 release from cultured monocyte-derived macrophages is inhibited by dexamethasone especially in M Φ 1, but ICS treatment did not change YKL-40 serum and sputum levels in COPD. These results indicate that YKL-40 expression could be used as a marker for M Φ 1 macrophages *in vitro*, but not for monitoring the effect of ICS in COPD.

INTRODUCTION

YKL-40 (or chitinase 3-like-1 [CHI3L1], breast regression protein [BRP]-39 or human cartilage glycoprotein-39 [HCgp-39]) is a chitinase-like protein which is found in humans [1]. It is expressed by various cell types, including neutrophils and macrophages [2-4], while macrophages have been identified as its main cellular source [2, 5]. Monocytes do not express YKL-40, and YKL-40 expression appears to be associated with later stages of macrophage differentiation [2, 6]. Although its biological function is largely unknown, YKL-40 has been suggested to play a major role in a variety of processes, including epithelial-mesenchymal transition, migration and proliferation of (malignant) cells, angiogenesis, tissue remodeling and inflammation [7-9]. Furthermore, YKL-40 has been implicated in several acute and chronic inflammatory diseases, including asthma and COPD [10, 11]. Several studies have shown that YKL-40 levels are higher in sputum and serum of COPD patients compared to asymptomatic smokers [12, 13].

These data suggest that macrophages may also be a major source of YKL-40 in inflammatory lung diseases such as COPD, a disease in which macrophages play an important role [14]. It is however unknown whether YKL-40 expression is restricted to a subset of macrophages. This is a relevant question, since macrophages constitute heterogeneous cell populations with various functions. Pro-inflammatory, or classically activated macrophages (type I, M Φ 1), show pro-inflammatory properties by secreting pro-inflammatory cytokines such as interleukin-12 (IL-12), have antigen presenting capacity and promote Th1 immunity. In contrast, anti-inflammatory, or alternatively activated macrophages (type II, M Φ 2), demonstrate anti-inflammatory characteristics with expression and secretion of anti-inflammatory cytokines, such as IL-10 and promote development of regulatory T cells [15]. Furthermore, Di Rosa *et al.* observed higher expression of YKL-40 in monocyte-derived M Φ 1 [16].

Dexamethasone strongly suppresses YKL-40 expression in cultured monocyte-derived macrophages [17]. In line with these findings, rheumatoid arthritis patients treated with methotrexate and prednisolone had lower serum YKL-40 concentrations compared to patients treated without prednisolone [18]. However, it is unknown if YKL-40 levels are influenced by treatment with inhaled corticosteroids (ICS) in COPD and could therefore be used to monitor treatment response. Furthermore, it is not known whether modulation by steroids is a direct genomic anti-inflammatory effect or due to e.g. epigenetic mechanisms [19-22].

Based on these observations we hypothesized that YKL-40 expression is directed by macrophage polarization, with a higher expression in monocyte-derived M Φ 1 compared to M Φ 2. Furthermore, we hypothesized that steroids decrease YKL-40 secretion and expression in M Φ 1 and that YKL-40 in serum and sputum of COPD patients is decreased by treatment with ICS.

METHODS

Cell culture

Monocytes were isolated from buffy coats of healthy blood donors (Sanquin Blood Bank, Leiden, The Netherlands) using anti-CD14 microbeads (Miltenyi Biotec, Auburn, CA, USA) according to the manufacturer's protocol. M Φ 1 and M Φ 2 were derived as described previously [23, 24]. Briefly, cells were cultured for six days in RPMI 1640 medium in 48 well plates (Invitrogen, Life Technologies, Bleiswijk, The Netherlands) containing 10% fetal calf serum (FCS, Invitrogen), 2mM L-glutamine, 100U/ml penicillin and 100 μ g/ml streptomycin (all Bio Whittaker, Walkersville, MD, USA) at 37°C in 5% CO₂ atmosphere with either GM-CSF (5ng/ml, Invitrogen) or M-CSF (50ng/ml, R&D Systems, Minneapolis, MN, USA) to obtain M Φ 1 and M Φ 2, respectively (13, 14). Differentiated macrophages were stimulated with the pro-inflammatory stimuli lipopolysaccharide (LPS, from *Pseudomonas aeruginosa*, 100ng/ml, Sigma-Aldrich, St. Louis, MO, USA), TNF- α (10ng/ml, Peprotech, Rocky Hill, NJ, USA) or oncostatin M (OSM, 100ng/ml, R&D Systems) for 24 hours. Dexamethasone (0.1, 0.3 and 1nM, Sigma) was added during differentiation at day 0, 3 and/or day 7. The demethylating agent 5-AZA-2'-deoxycytidine (5-AZA, 0.1, 1 and 10 μ M, Sigma) was added during differentiation. Every day 100 μ l per well was removed and replaced by fresh medium containing growth factors and 5-AZA.

GLUCOLD study

Serum and sputum supernatants were obtained from patients with moderate to severe COPD who participated in the GLUCOLD (Groningen and Leiden Universities Corticosteroids in Obstructive Lung Disease) study [25]. Patients were steroid-naïve at baseline and were subsequently randomized to one of four inhaled treatments, all twice daily: 6- or 30-month

fluticasone propionate dry-powder inhaler (500µg, group 1 and 2, respectively), 30-month fluticasone with salmeterol (500/50µg, group 3) or 30-month placebo (group 4). In this mechanistic study, we only used data from the compliant patients ($\geq 70\%$ of the prescribed dose of treatment) of groups 2 and 3 combined to increase power, and group 4. At baseline and after 30 months of treatment, serum and sputum samples were collected. Sputum induction and processing were performed as previously described [26, 27]. Cell free supernatants of serum and sputum were stored at -80°C . The ethics committees of Leiden University Medical Center and University Medical Center Groningen approved the study and all patients provided written informed consent.

Enzyme-linked Immunosorbent Assay (ELISA)

Commercially available ELISA kits were used to detect IL-12p40 (IL-12/ IL-23p40, R&D Systems; sensitivity 62.5 pg/ml) and IL-10 (Sanquin, Amsterdam, The Netherlands; sensitivity 4.1 pg/ml), to confirm that the monocytes were adequately differentiated towards M Φ 1 and M Φ 2, respectively (Figure 1A). YKL-40 ELISA (R&D Systems; sensitivity 16 pg/ml [10]) was performed on cell culture supernatant, serum and sputum supernatant. The absorbance was measured at 450nm using a Microplate reader (model 680; Bio-Rad, Hercules, CA, USA) and Microplate Manager software (version 5.2.1, Bio-Rad).

Flow cytometry

Cell surface markers were assessed by standard flow cytometry using a FACS Calibur cytometer (Becton and Dickinson, La Jolla, CA, USA) and CellQuest Pro software after staining with specific APC-conjugated CD163 and CD14 (both BD Biosciences/ Pharmingen (Temse, Belgium), FITC-conjugated CD68 (eBioscience, Vienna, Austria) and/or goat-anti-human YKL-40 (R&D systems) detected by Alexa Fluor 594 F(ab')₂ fragment of goat anti-mouse (Invitrogen) as secondary antibody. Cells were incubated with the antibodies for 30 minutes on ice in PBS containing 0.5% BSA (w/v) and 0.2% sodium azide (w/v) (both Sigma). After fixation with Cytotfix/ Cytoperm buffer, intracellular staining was performed in Perm/ Wash buffer (both BD Biosciences). Flow cytometric analysis confirmed that the differentiated monocytes were CD14⁺ and CD68⁺, and that the majority of M Φ 2 were CD163⁺ (Figure 1B). Therefore, we concluded that the monocytes were properly differentiated into M Φ 1 and M Φ 2 cells.

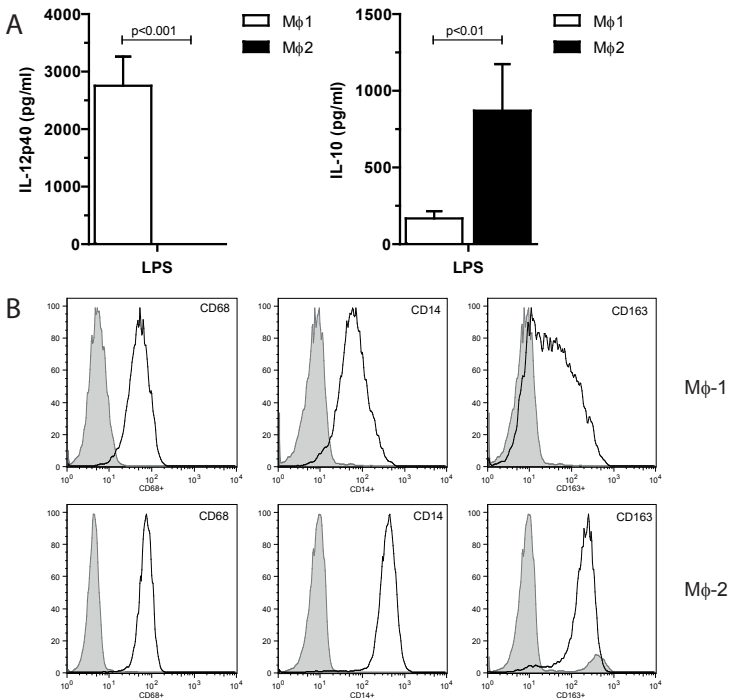

Figure 1: Characterization of differentiated MΦ1 and MΦ2. Figure 1A: IL-12p40 (left panel) and IL-10 (right panel) in supernatants of MΦ1 and MΦ2, respectively, stimulated with LPS for 24 hours. Data represent means with SEM of 6 donors. Figure 1B: Flow cytometry analysis for CD68, CD14 and CD163 (left, middle and right panel, respectively) for MΦ1 and MΦ2 (upper and lower panel, respectively).

Immunofluorescence staining

YKL-40 and CD68 expression in sputum cytopins was demonstrated using immunofluorescence. Cytopins were fixed in 4% formaldehyde in PBS for 30 minutes, followed by antigen retrieval in citrate solution pH6.0 (DAKO, Glostrup, Denmark) for 30 minutes and cooled on ice. The primary antibodies goat-anti-human YKL-40 (R&D systems, dilution 1:25) and mouse-anti-human CD68 (clone PG-M1, DAKO, dilution 1:50), diluted in PBS/ 1% BSA (w/v) were incubated together overnight. Alexa Fluor568 donkey-anti-goat and Alexa Fluor 488 donkey-anti-mouse (Invitrogen, Eugene, OR, dilution of both 1:200) were incubated in a dark environment for 30 minutes. The cytopins were covered with Vectashield with DAPI (Vector Laboratories, Inc. Burlingame, CA, USA). Photographs were taken with a confocal microscope.

Quantitative reverse-transcriptase polymerase chain reaction (qPCR)

RNA was isolated using Qiagen RNeasy mini kit (Qiagen, Venlo, The Netherlands) and cDNA was synthesized in equal amounts per experiment. Quantitative reverse-transcriptase polymerase chain reaction (qPCR) was performed with the primers for YKL-40 and LL-37 as presented in Table 1. QPCR was performed on the iCycler PCR device using iQ SYBR Green Supermix (Bio-Rad) for 40 cycles at 58°C. Relative mRNA concentrations of ACTB and ATP5B (GeNorm, PrimerDesign Ltd., Southampton, UK) were used as housekeeping genes for human genes.

Table 1: Primer pairs used for quantitative reverse-transcriptase polymerase chain reaction (qPCR).

	Forward	Reverse
YKL-40 (CHI3L1) (154 base pairs)	CTG TGG GGA TAG TGA GGC AT	CTT GCC AAA ATG GTG TCC TT
LL-37 (CAMP) (249 base pairs)	TCA TTG CCC AGG TCC TCA G	TCC CCA TAC ACC GCT TCA C

Statistical analysis

Differences within one cell type and between cell types were analyzed by one-way and two-way ANOVA, respectively. Paired and unpaired tests were used for evaluating YKL-40 levels in serum and sputum within and between treatments, respectively, using only data from subjects with availability of samples from both baseline and 30 months. Statistical analysis was performed with SPSS 22.0 software (SPSS Inc., Chicago, IL). Data are presented as means with standard error of the mean (SEM) for *in vitro* experiments and means with standard deviations (SD) for serum and sputum samples. Differences at p-values ≤ 0.05 were inferred as statistically significant.

RESULTS

MΦ1 produce more YKL-40 compared to MΦ2

Secretion of YKL-40 by MΦ1 was markedly higher compared to MΦ2 ($P < 0.001$) and not further increased by stimulation for 24 hours with 100ng/ml LPS compared to medium ($P < 0.001$; Figure 2A, left panel). qPCR confirmed these results, i.e. MΦ1 express more YKL-40 than MΦ2 with and without LPS stimulation (10-fold higher in MΦ1 vs MΦ2, $P < 0.001$; Figure 2A, right panel), with a trend towards more YKL-40 expression in LPS-stimulated MΦ1 ($P < 0.1$). Flow cytometry analysis also showed that MΦ1 cells express more YKL-40 compared to MΦ2 (Figure 2B). In addition, MΦ1 secreted more YKL-40 compared to MΦ2 which was irrespective of further stimulation with TNF- α , and OSM for 24 or 48 hours, respectively (all $P < 0.001$, Figure 2C). Immunofluorescence staining showed that only a minority of macrophages in sputum of COPD patients was positive for YKL-40 as shown by co-staining with CD68 (Figure 2D).

YKL-40 expression is inhibited by dexamethasone

To investigate the effect of steroids on macrophage YKL-40 expression, we first assessed its effect on expression of the MΦ1 and MΦ2 markers IL-12p40 and IL-10. Whereas dexamethasone did not affect IL-10 secretion, it inhibited IL-12p40 secretion, especially when added at day 0 (Figure 3A and B, respectively). In line with these findings, dexamethasone also dose-dependently inhibited YKL-40 expression and secretion mainly in MΦ1 (Figure 4A and B, respectively). Again this effect was most pronounced when dexamethasone was added from the start of the differentiation at day 0 (Figures 4A and B, left panel). Adding dexamethasone at later time points (day 3 or day 7) showed a trend for lower YKL-40 expression and secretion (Figures 4A and B, middle and right panel, respectively), but failed to reach significance.

We have previously demonstrated that the human cathelicidin antimicrobial peptide hCAP/LL-37 directs macrophage differentiation towards MΦ1 cells [28]. In the course of the latter studies we also noted that hCAP18/LL-37 is preferentially expressed in MΦ1 cells (unpublished results). In the present study, we therefore used LL-37 expression for a comparison with YKL-40 expression. In line with the findings for IL-12p40 and YKL-40, the expression of LL-37 was also dose-dependently reduced by increasing doses of dexamethasone when added on day 0, but not on day 3 or day 7 (Figure 4C).

Collectively these data indicate that dexamethasone inhibits YKL-40 expression, but that this effect is most likely explained by a more generic effect on MΦ1 development and is not selective for YKL-40 expression.

Figure 2: MΦ1 produce more YKL-40 compared to MΦ2. Figure 2A: YKL-40 secretion measured by ELISA (left panel, 6 donors) and mRNA levels (normalized expression, right panel, 5 donors) in MΦ1 and MΦ2 after medium and LPS stimulation for 24 hours. Figure 3: IL-12p40 secretion is dose-dependently inhibited by dexamethasone when added on day 0. IL-10 and IL-12p40 secretion with addition of dexamethasone at day 0, 3 and 7 of differentiation (0.1, 0.3 and 1nM) (Figure 3A and B, left, middle and right panel, respectively). Data represent means and SEM (n= 3 donors). * p≤0.05, ** P<0.01 or *** P<0.001: between M01 to M02 with corresponding stimulus. § p≤0.05 or § P<0.001 between M01 at different concentrations of dexamethasone.

YKL-40 expression is not affected by the demethylating agent 5-AZA

Epigenetic mechanisms may contribute to CHI3L1 expression. This is supported by the finding of a single-nucleotide polymorphism (SNP) localized near the CpG island in the promoter region of the CHI3L1 gene, which is associated with YKL-40 expression [19, 20]. To evaluate whether YKL-40 expression in monocyte-derived macrophages is influenced by the methylation status of the CHI3L1 gene, macrophages were generated in the presence of the demethylating agent 5-AZA. We first observed that 5-AZA inhibited IL-12p40 secretion, and to a smaller extent also IL-10 secretion (Figures 5A and B, respectively). In contrast, YKL-40 protein secretion and expression was not significantly affected by 5-AZA, although it needs to be noted that the highest concentration resulted in cell toxicity (Figures 5C and D, respectively).

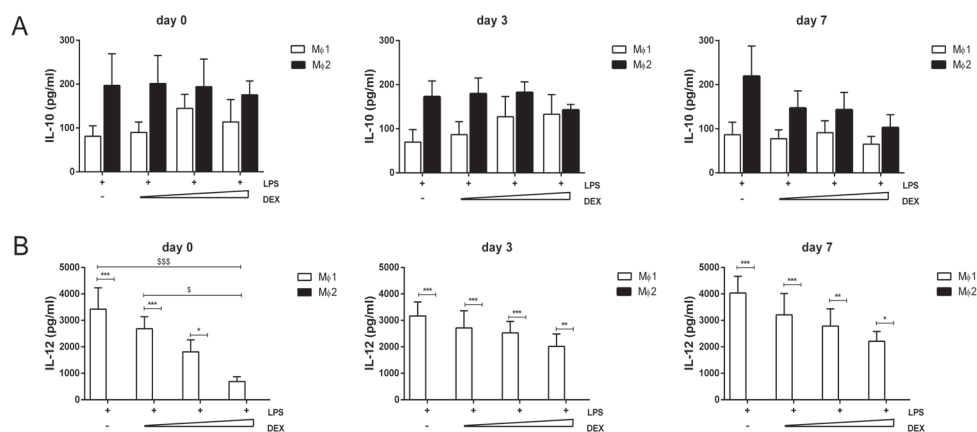

Figure 4: YKL-40 expression and protein secretion is inhibited by dexamethasone. YKL-40 mRNA levels (normalized expression) and YKL-40 protein secretion (figure 4A and B, respectively) in M01 and M02 with addition of dexamethasone at day 0, 3 and 7 of differentiation (0.1, 0.3 and 1nM) (left, middle and right panel, respectively). LL-37 mRNA levels (normalized expression) after 0, 3 and 7 days of differentiation with dexamethasone (0.1, 0.3 and 1nM) (figure 4C left, middle and right panel, respectively). YKL-40 levels in serum and sputum of COPD patients are not changed by treatment with inhaled corticosteroids

We next used samples of the GLUCOLD study to investigate the effects of ICS treatment on serum and sputum YKL-40 levels in COPD patients. Baseline characteristics between the group of moderate to severe COPD patients treated with ICS and placebo were not significantly different as shown in Table 2. Of the 75 compliant patients, 70 serum samples and 59 induced sputum samples at baseline were available and suitable for analysis. Serum YKL-40 levels at baseline were significantly higher compared to sputum levels at baseline (respectively median 71 ng/ml versus 29 ng/ml, P<0.001). ICS treatment did not significantly change YKL-40 levels in serum and sputum compared to placebo (both p>0.05; Figure 6).

Table 2: Patient characteristics of compliant patients at baseline of the GLUCOLD study. The ICS group is a combination of the original 30-month fluticasone and 30-month fluticasone with salmeterol groups.

Data represent mean with SD, median with interquartile range or numbers.

GLUCOLD: Groningen and Leiden Universities Corticosteroids in Obstructive Lung Disease. ICS: Inhaled corticosteroids. FEV₁: Forced Expiratory Volume in 1 second. IVC: Inspiratory vital capacity. Pred: predicted.

Figure 6: Sputum and serum YKL-40 protein levels of COPD patients before and after ICS treatment. YKL-40 levels in sputum and serum at baseline (0) and after 30 months (30m) of inhaled corticosteroids (ICS) and placebo. For comparison of the levels between baseline and 30 months, we only included patients from whom samples were available at both time points (paired data). Each dot represent a single patient, red horizontal bars represent medians.

DISCUSSION

This study shows that secretion and expression of YKL-40, a chitinase-like protein, is higher in *in vitro* generated monocyte-derived M Φ 1 than in M Φ 2, and that YKL-40 expression is not further increased upon stimulation with several pro-inflammatory stimuli. In addition, YKL-40 release *in vitro* is strongly inhibited by dexamethasone especially in M Φ 1, most likely due to an effect on differentiation. Addition of the demethylating agent 5-AZA did not significantly decrease YKL-40 release, but did decrease IL-12p40 production by M Φ 1 and to a smaller extent IL-10 production by M Φ 2 cells. YKL-40 levels in serum were significantly higher in serum than in sputum of COPD patients. Treatment of these patients for 2.5 years with inhaled corticosteroids did not significantly change serum and sputum YKL-40 levels compared to placebo. These results suggest that YKL-40 is a promising pro-inflammatory marker in *in vitro* cultured pro-inflammatory macrophages, but is less suitable for monitoring *in vivo* effect of treatment with steroids on YKL-40 in serum and sputum of COPD patients.

We show that YKL-40 is a novel marker of *in vitro* cultured monocyte-derived M Φ 1, which is independent of LPS, OSM and TNF- α . This is an important observation, since many established M Φ 1 markers require additional stimulation to induce expression. Our data confirm and extend previous results [16, 17, 29], reporting higher CHI3L1 expression in classically activated macrophages compared to alternatively activated macrophages. In the latter studies, in contrast to our study, interferon-gamma (IFN- γ) and IL-4 were used for M Φ 1 and M Φ 2 polarization, respectively [16, 17]. We extended these data by differentiating monocytes with GM-CSF and M-CSF into M Φ 1 and M Φ 2, respectively, and explored the effect of further stimulation after differentiation with several pro-inflammatory stimuli. We found that dexamethasone efficiently suppressed YKL-40 expression and secretion in M Φ 1, but that this was mainly explained by an inhibitory effect of dexamethasone on M Φ 1 differentiation, thus extending previous results [17].

We found that YKL-40 levels in serum were higher than in sputum of COPD patients. Serum YKL-40 levels of our group of patients were comparable with previous studies [13, 30, 31]. However, sputum YKL-40 levels with sputum processed using the whole sample method, were considerably lower than in studies using the selected plug method [12]. This is most likely due to dilution which is inherent to the whole sample method. After long-term treatment with ICS, we did not detect a significant change in YKL-40 levels in serum and sputum compared to placebo. To our knowledge, this is the first study that evaluates the

long-term effect of ICS in serum and sputum YKL-40 levels of COPD patients. Therefore, this study presents new *in vitro* and *in vivo* data that may help to provide insight in the function of YKL-40.

The mechanisms that regulate YKL-40 expression in health and disease are partly understood. It has been demonstrated that YKL-40 expression is absent in monocytes, and markedly induced during macrophage differentiation, especially during the later stages of differentiation [2]. Promotor analysis of the *CHI3L1* gene revealed that especially Sp1, an ubiquitous transcription factor, is important for *CHI3L1* gene expression [6]. Possibly epigenetic mechanisms also contribute to *CHI3L1* expression. This is supported by the finding of a SNP localized near the CpG island in the promoter region of the *CHI3L1* gene, which is associated with YKL-40 expression [19, 20, 32]. Furthermore, hypomethylation of the *CHI3L1* gene in rheumatoid arthritis is associated with increased expression of YKL-40 [33, 34]. Therefore, *CHI3L1* gene expression may be regulated by transcription factors such as Sp1 and by DNA methylation status. Our observations with 5-AZA treatment do not support a role for DNA methylation in the expression of YKL-40 in M Φ 1. Further studies into methylation status of the promotor of YKL-40, the role of histone modification and microRNAs are needed to define a role of epigenetic mechanisms in the expression of YKL-40 in (lung) macrophages.

The strength of our study is that it describes a thorough evaluation of a novel, potential pro-inflammatory macrophage marker using both *in vitro* and *in vivo* approaches. Well-characterized patients with COPD used long-term, randomized, placebo-controlled treatment with ICS. However, we were unable to detect an effect of a randomized treatment with ICS on YKL-40 serum and sputum levels. Nevertheless, our study has some limitations. First, we used *in vitro* cultured monocyte-derived macrophages from whole blood of healthy subjects that were differentiated towards M Φ 1 and M Φ 2 instead of lung-derived (e.g. alveolar) macrophages that were differentiated under the influence of the local environment. Since the culture systems do not fully reflect *in vitro* differentiation of macrophage subsets [35, 36], it needs to be noted that the effect of steroids on lung macrophages may differ from that on *in vitro* differentiated macrophages. Furthermore, *in vivo* a heterogeneous and intermediate macrophage population exists [37], which complicates the comparison with *in vitro* generated M Φ subsets. We therefore cannot formally exclude the possibility that this has contributed to our inability to detect an effect of inhaled corticosteroids on serum and sputum YKL-40 levels. Second, the demethylating agent 5-AZA demonstrated cell toxicity which might have influenced our results. However, we found a dose-dependent inhibition of YKL-40 expression and secretion, suggesting that DNA methylation status may contribute to regulation of YKL-40 expression in M Φ 1, which is in line with studies posing that methylation

of a part of the CpG island of the *CHI3L1* gene is associated with YKL-40 levels [19, 32].

How can we explain that serum and sputum YKL-40 levels of COPD patients were not significantly changed after long-term ICS treatment compared to placebo? This is unexpected since serum YKL-40 levels of rheumatoid arthritis patients rapidly decreased after one week of prednisolone [18]. However, the amount of inhaled fluticasone that reaches the systemic circulation is low [38], which could explain why serum YKL-40 levels did not significantly change with ICS therapy. In addition, lung macrophages in COPD have reduced glucocorticoid sensitivity [39, 40].

CONCLUSION

YKL-40 is mainly expressed and secreted by M Φ 1 and is not further increased by pro-inflammatory stimuli. YKL-40 release is inhibited by dexamethasone in M Φ 1 *in vitro*, whereas long-term treatment of COPD patients with inhaled corticosteroids did not significantly change YKL-40 levels in serum and sputum. This suggests that YKL-40 is a potential marker for *in vitro* cultured pro-inflammatory macrophages and is not a valuable biomarker in serum and sputum of patients with COPD treated with inhaled corticosteroids.
