Safety and efficacy after immunization with *Plasmodium falciparum* sporozoites in the controlled human malaria infection model

- 1) Chemoprophylaxis and sporozoites immunisation (CPS) has proven to be a reproducible and robust strategy to induce sterile homologous protection against *P. falciparum* in healthy volunteers (this thesis)
- 2) The use of mefloquine to induce sterile protection in CPS, compared to chloroquine, has proven to be similarly safe, immunogenic and protective (this thesis)
- 3) The striking efficiency of homologous protection in CPS has yet to be demonstrated for heterologous protection required for use in malaria endemic areas (this thesis)
- qPCR-based initiation of anti-malarial treatment in the controlled human malaria infection model, instead of microscopic examination of the thick smear, reduces symptoms and increases safety for volunteers (this thesis)
- 5) Plasmodium infected individuals change in human odor and produce greater amounts of aldehydes and enhances the attractiveness of mosquitoes [1]
- 6) Intradermal administration of sporozoites, compared to the intravenous route, provides less protective immunity due to increased regulatory immune responses and is independent of parasite liver load [2]
- 7) Malaria eradication will depend on the effective implementation of the combination of all current existing anti-malaria tools and a highly efficacious vaccine [3]
- 8) Don't be afraid to bite on a giant, learn from the mosquito (Bangambiki Habyarimana, Pearls of Eternity 2016)*
- 9) Two things are infinite. The universe and human stupidity; and I am not sure about the former (Albert Einstein 1947)*
- 10) Wat er ook gebeurt, altijd blijven lachen... (Bas en Aad van Toor 1977)\$
