Title: Stochastic and deterministic algorithms for continuous black-box optimization

Issue Date: 2018-11-01

## Propositions accompanying the thesis

# Stochastic and Deterministic Algorithms for Continuous Black-Box Optimization

### Hao Wang

- 1. The effectiveness and efficiency of a stochastic variation can be judged by the discrepancy of the sample generated from it. *Chapter 2*.
- 2. When using Kriging for modeling, we should always question about the assumption that the target function can be represented in the function space induced by Kriging. *Chapter 3*.
- 3. In modeling, it is better to build fine-grained local models and construct a global model by combining the local ones. This makes it possible to extend Kriging for big data sets. *Chapter 3*.
- 4. The balance between exploration and exploitation can be controlled carefully by using the weighted combination of moments on the Kriging model. *Chapter 4*.
- 5. Niching methods can facilitate the parallelization of infill criteria, with relatively small computational overhead. *Chapter 4*.
- 6. In hypervolume indicator gradient method, adaptively controlling the stepsize of the steepest descent direction speeds up the convergence significantly. *Chapter 5*
- 7. The so-called Kriging mean squared error measures how well the assumed stochastic process is approximated by finite samples.
- 8. During the optimization process, it is beneficial to infer the structure and feature of the objective function online.
- 9. The convergence rate of efficient global optimization is affected by the contraction rate of the Kriging model and the error that occurs when optimizing the infill criterion.
- 10. You reap, what you sow. You get out, what you put in.
