Comprehensive structure-activity-relationship of azaindoles as highly potent FLT3 inhibitors*

Introduction

Acute myeloid leukemia (AML) is a cancer of the blood and bone marrow that is characterized by a failure in differentiation of stem cells during hematopoiesis, resulting in flooding of the bloodstream with immature myeloid blood cells. These blast cells fatally disrupt normal hematopoietic function and their abundance in blood obstruct the normal flow in capillaries resulting in a high mortality.1,2 While in younger patients cure rates can reach up to 35-40%, elderly patients, who are often unable to cope with the intensive chemotherapy regimen, do not experience this benefit.3 AML is a genetically diverse disease, but in 20-30% of patients an internal tandem duplication (ITD) in the juxtamembrane domain of the Fms-like tyrosine kinase 3 (FLT3) receptor has been identified as a driver mutation.4,5 The validation of FLT3 as a drug target led to clinical development of several small molecule inhibitors, culminating in the recent FDA approval of midostaurin for treatment of FLT3-dependent AML in conjunction with standard treatment.6–9 Although the initial response to treatment with FLT3 inhibitors shows therapeutic promise, many AML patients relapse due to the emergence of drug-resistant cancer cells.10–12 Resistance-inducing mutations have thus far been observed in

treatments with several FLT3 inhibitors, among which the highly potent experimental drug quizartinib.\textsuperscript{12–14} The discovery of new chemical entities to target FLT3 represents, therefore, a medical need.

\textit{N}-[2-(\textit{p}-Bromocinnamylamino)ethyl]-5-isoquinolinesulfonamide (H-89) is a prototypical and intensely-studied kinase inhibitor (Figure 1A). It was one of the first non-natural, synthetic inhibitors that competitively inhibited the binding of ATP to the structurally conserved binding domain of cAMP-dependent protein kinase (PKA).\textsuperscript{16,17} The binding mode of H-89 to PKA has been studied in great detail at the atomic level using crystallization studies.\textsuperscript{18} This contributed to the understanding of kinase function and provided general principles to develop drug-like kinase inhibitors. The isoquinoline sulfonamide mimics the binding mode of adenosine. The nitrogen of the isoquinoline ring forms a crucial H-bond bridge to the backbone of Val-123, located in the hinge region of PKA.\textsuperscript{18} This binding mode of H-89 is not specific to PKA, but has also been observed with Haspin, as shown in structural data (PDB: 3FMD). Furthermore, H-89 activity has been shown for several other kinases, including S6K1, MSK1 and ROCK-II.\textsuperscript{19,20} Consequently, H-89 is used as a starting point in several drug discovery programs. For example, this lab has previously described the use of H-89 and its analogs as RAC-alpha serine/threonine-protein kinase (AKT1) inhibitors to combat bacterial infections, such as \textit{Salmonella typhimurium} and \textit{Mycobacterium tuberculosis}.\textsuperscript{15,21} During the hit optimization program of H-89 analogs as AKT1 inhibitors, four compounds (1-4) were identified that demonstrated substantial activity against FLT3 (Figure 1B).\textsuperscript{15} In this chapter the optimization and structure-activity relationships of H-89-derived compounds as new FLT3 inhibitors is presented.

\section*{Results and Discussion}

To confirm the structure and activity of compound 1, the synthesis was started with the commercially available building blocks as outlined in Scheme 1. After methylation and
reduction, the resulting alcohol was exchanged for a chlorine and a trityl protected ethylenediamine linker was introduced via nucleophilic substitution. Subsequent Boc-protection, Suzuki-coupling with 3-pyridinylboronic acid and trityl-deprotection yielded the primary amine, which could be coupled with isoquinoline sulfonfyl chloride to provide the desired product 1. The activity of compound 1 was confirmed in a biochemical assay using purified, recombinantly expressed human FLT3 with a time-resolved fluorescence resonance energy transfer (FRET) method. Compound 1 showed potent inhibition with a half maximum inhibitory concentration (IC\(_{50}\)) in the low nanomolar range (pIC\(_{50}\) = 8.02 ± 0.05), which was comparable to the inhibitory activity of the reference inhibitor quizartinib (pIC\(_{50}\) = 8.30 ± 0.07). Compound 1 demonstrated favorable physico-chemical properties with a molecular weight (MW) of 445 and a logD (pH 7.4) of 1.5.\(^{22}\) This resulted in a lipophilic efficiency (LipE = pIC\(_{50}\) - logD) of 6.5.\(^{23}\) In summary, compound 1 was defined as an excellent starting point to develop new FLT3 inhibitors.

A topological exploration of the structure-activity relationship of isoquinolinesulfonamides was employed guided by the observed binding mode of H-89 in other kinases.\(^{18}\) First, the isoquinoline substituent was replaced by various other hinge binding moieties inspired by kinase drugs, including indolones (sunitinib and nintedanib),\(^{24-27}\) aminoisouquinolines (crizotinib and palbociclib),\(^{24,28,29}\) indazoles (axitinib)\(^{24,30}\) and picolinamides (sorafenib).\(^{24,31,32}\) The analogs (5-16) were synthesized in a similar manner as compound 1 using a palladium-catalyzed sulfination of heteroaryl halides and subsequent coupling with the primary amine as shown in Scheme 1.\(^{33}\) Interestingly, compounds 5-12 displayed similar or slightly weaker activity compared to compound 1 with a range of pIC\(_{50}\)s between 7.6 and 8.0 (Table 1). Indazolone 6 was the most potent compound of the series with a pIC\(_{50}\) of 8.01 ± 0.08.
Moreover, substantially more polar groups such as picolinamide were well tolerated (as observed in compound 10), resulting in a high lipE of 7.6. Surprisingly, the nitrogen atom, which plays an important role in the hinge binding to other kinases, was not required for activity. Compounds 13 and 14 retained activity with a pIC\textsubscript{50} of 7.21 ± 0.34 and 6.19 ± 0.15, respectively. The same was true for the nitro and amino phenyl derivatives 15 and 16. All together, these results suggested that the binding orientation of the isoquinolinesulfonamides might be different than the one of H-89 in PKA. It was envisioned that the nitrogen atom of the pyridyl ring could act as a potential H-bond acceptor to interact with the hinge region,

which may potentially explain the activity of compounds 13-16. To test this hypothesis compounds (17-18), in which the pyridine ring was substituted for a carbacycle, were synthesized (SI Scheme 1). The pIC$_{50}$ of these novel derivatives dropped to < 5 (Table 1). This suggested that the nitrogen in the pyridine is indeed important for the interaction with FLT3 and the isoquinolinesulfonamide may have a flipped binding orientation in the ATP-pocket of FLT3 compared to PKA.

To further understand the SAR of our chemical series, the importance of the linker between the isoquinoline and the pyridyl moieties was investigated (19-31). The results from this study are summarized in Table 2. The synthetic schemes for these compounds (19-31) are shown in
the SI (SI Scheme 1-4). Several analogs were made to investigate possible hydrogen bond donor capability of the sulfonamide and secondary amine group. To this end, the nitrogens of sulfonamide (19), amine (20) or both (21) were substituted with a methyl group. This led to a > 10-fold drop in potency for all compounds, which indicated that these NH donors could be important for the interaction with FLT3. Next, the linker length between the secondary amine and the phenyl was investigated. Compounds with reduced length of one (22) and two (23) methylene groups showed decreased activity. The importance of the basicity of the linker moiety was tested by replacing the amine with an ether (24), amide (25), or a methylene (26) containing linker. 24 and 25 were equally active as the corresponding amine derivative, while 26 was > 10-fold less active (Table 2). These results suggested that the basic center of the linker is not required. Of note, reduction of the double bond (27 - 29) in the linker resulted in an almost identical inhibitory activity as the parent compound, whereas increasing the conformational restriction in compound 30 reduced its activity. This indicated that the reduced conformational flexibility by the double bond in compound 1 is not beneficial for its activity as has recently been noted for other kinase inhibitors.34 Finally, the substitution of the sulfonamide for an amide did result in an inactive compound (31) (pIC<sub>50</sub> < 5), which could possibly be due to a difference in the spatial orientation of the (sulfon)amide substituents. These data indicate that a flexible linker of 6 atoms with or without a basic amine is optimal between the sulfonamide and phenyl-pyridyl rings.

Having established the optimal linker features, an additional array of compounds (32-37) was synthesized in which the pyridyl ring was replaced with other (substituted) heteroaryls to optimize the hinge-binding interaction (Scheme 2 and SI Scheme 5). In contrast to the isoquinoline replacements, a wide range of activities was observed (pIC₅₀: 5 – 8.9) (Table 3). While the picolinamide variations (34-35) were inactive (pIC₅₀ < 5), the azaindoles 36 and 37 demonstrated a significantly increased pIC₅₀ of 8.87 ± 0.06 and 8.78 ± 0.05, respectively. Of note, 37 demonstrated a LipE of 6.7. Altogether, the optimization of the potential hinge-binding pyridyl moiety resulted in the discovery of the azaindoles as a potent FLT3 inhibitor scaffold.

Next, a matched-molecular pair analysis was performed using the azaindole scaffold with amide (38-49) and amine linker (50-54) series<sup>35</sup>. The goal was to study the influence of the substitution pattern of the phenyl ring<sup>36</sup>. Compounds (38-54) were prepared as shown in Scheme 2. Compounds with electron-withdrawing groups, such as Cl (39), p-NO<sub>2</sub> (43), p-F (45), or electron donating groups (p-Me (41) and p-OMe (42)) both displayed high potency (pIC<sub>50</sub> > 8.0). No correlation could be found between the Hammett constants of the substituents and the activity of the compounds (SI Figure 1). In fact, non-substituted compound 38 was the most potent compound identified in this study with a pIC<sub>50</sub> of 9.49 ± 0.08. The matched-molecular pair analysis of LipE values of the amine and amide series showed good correlation, which supports the hypothesis that both series bind in a similar fashion to FLT3 (Figure 2).

Finally, to explain our structure activity relationships a structure based study was performed with compound 1 and compound 38 using a published DFG-out crystal structure (4RT7), and a DFG-in model (see methods). Induced fit docking was performed in combination with an previously established binding pose metadynamics protocol\textsuperscript{45}, in order to determine a feasible binding mode. On the basis of these results and overlap in binding mode with quizartinib (SI Figure 2) it was established that compound 1 and compound 38 bind DFG-out (Figure 3A). The pyridine moiety of 1 is engaged in a hydrogen bond interaction with the backbone of C694 (hinge) and the adjacent phenyl engages in a π-interaction with F691 (Figure 3A). Moreover, in the induced fit docking, no poses were observed in which the isoquinoline interacted with the hinge of FLT3. As shown in Figure 3B the resulting docking pose of 38 is similar to the binding mode of 1 with an additional hydrogen-bond-interaction to C694, which may explain the increased potency. To conclude, the observed binding mode is in agreement with the obtained structure activity relations.
Comprehensive structure-activity-relationship of azaindoles as highly potent FLT3 inhibitors

Figure 3: Proposed “flipped” binding mode of 1 and 38 in FLT3. (A-left) 1 and (B-left) 38 docked in FLT3 crystal structure (PDB: 4RT7) On the right a 2D-interaction diagram is shown depicting the interactions between the ligand and FLT3.

In summary, azaindole 38 was identified as a new, highly potent inhibitor of FLT3-ITD with favorable physico-chemical properties. Our structure-activity relationships and modeling studies suggest that 38 has an alternative flipped binding mode compared to other kinase inhibitors derived from the prototypical kinase inhibitor H-89. 38 forms an excellent starting point for further lead optimization studies to obtain clinical candidates to modulate FLT3-ITD in AML patients.
Experimental

Biochemical Evaluation of FLT3 inhibitors

In a 384-wells plate (PerkinElmer 384 Flat White), 5 µL kinase/peptide mix (0.06 ng/µL FLT3 (Life Technologies; PV3182; Lot: 1614759F), 200 nM peptide (PerkinElmer; Lance® Ultra UltraLightTM TK-peptide; TRFO127-M; Lot: 2178856)) in assay buffer (50 mM HEPES pH 7.5, 1 mM EGTA, 10 mM MgCl₂, 0.01% Tween-20, 2 mM DTT) was dispensed. Separately inhibitor solutions (10 µM – 0.1 pM) were prepared in assay buffer containing 400 µM ATP and 1% DMSO. 5 µL of these solutions were dispensed and the plate was incubated in the dark at room temperature. After 90 minutes the reaction was quenched by the addition of 10 µL of 20 mM EDTA containing 4 nM antibody (PerkinElmer; Lance® Eu-W1024-anti-phosphotyrosine(PT66); AD0068; Lot: 2342358). After mixing, samples were incubated for 60 minutes in the dark. The FRET fluorescence was measured on a Tecan Infinite M1000 Pro plate reader (excitation 320 nm, emission donor 615 nm, emission acceptor 665 nm). Data was processed using Microsoft Excel 2016, pIC₅₀ values were fitted using GraphPad Prism 7.0. Final assay concentrations during reaction: 200 µM ATP, 0.03 ng/µL FLT3, 100 nM Lance TK-peptide, 0.5% DMSO. Compounds were tested in n=2 and N=2.

Structure based modeling on FLT3

All structure based modeling was performed in the Schrödinger suite (Schrödinger Release 2017-4: Maestro, Schrödinger, LLC, New York, NY, 2017). Crystal structures were prepared using the protein preparation wizard, ligands were prepared using LigPrep. Both the DFG-out structure co-crystallized with quizartinib (4RT7) and a DFG-in model were used in order to dock our initial compound. The DFG-in model was constructed on the basis of 4RT7 and 3LCD, in a similar fashion as has been done before, using the knowledge based potential in prime. Docking was done using induced fit docking and using H-bond constraints on C694. In order to determine to correct binding pose, induced fit docking was followed by the conformer cluster script, using the Kelley criterion to determine the optimal number of clusters. The highest scoring poses of every cluster were used in a previously published workflow to determine binding poses, which is based on metadynamics. The highest scoring pose was selected by adding the Metadynamics CompScore to the docking score. Based on this workflow the highest scoring pose was visualized and rendered using PyMol.

Synthetic Procedures

Solvents were purchased from Biosolve, Sigma Aldrich or Fluka and, if necessary dried over 3Å or 4Å molecular sieves. Reagents purchased from chemical suppliers were used without further purification, unless stated otherwise. Oxygen or H₂O sensitive reactions were performed under argon or nitrogen atmosphere and/or under exclusion of H₂O. Reactions were followed by thin layer chromatography which was performed using TLC silica gel 60 F₂₄₅ on aluminium sheets, supplied by Merck. Compounds were visualized by UV absorption (254 nm) or spray reagent (permanganate (5 g/L KMnO₄, 25 g/L K₂CO₃)). TLCMS was measured with a thin layer chromatography-mass spectrometer (Advion, Epression LCMS; Advion, Plate Express). ¹H- and ¹³C-NMR spectra were performed on one of the following Bruker spectrometers: DPX 300 NMR spectrometer (300 MHz), equipped with 5mm-BBO-z-gradient-probe; AV-400 NMR spectrometer (400 MHz), equipped with 5mm-BBO-z-gradient-probe; AV-500 NMR spectrometer (500 MHz), equipped with BBFO-z-gradient-probe; AV-600 NMR spectrometer (600 MHz), equipped with 5mm-Cryo-z-gradient probe. NMR spectra were
measured in deuterated methanol, chloroform or DMSO and were referenced to the residual protonated solvent signals as internal standards (chloroform-$d_4 = 7.260\ (^{1}\text{H}), 77.160\ (^{13}\text{C});$ methanol-$d_4 = 3.310\ (^{1}\text{H}), 49.000\ (^{13}\text{C});$ DMSO-$d_6 = 2.500\ (^{1}\text{H}), 39.520\ (^{13}\text{C})$). Signals multiplicities are written as s (singlet), bs (broad singlet), d (doublet), t (triplet), q (quartet), p (pentet) or m (multiplet). Coupling constants ($J$) are given in Hz. Preparative HPLC (Waters, 515 HPLC pump M; Waters, 515 HPLC pump L; Waters, 2767 sample manager; Waters SFO System Fluidics Organizer; Waters Acquity Ultra Performance LC, SQ Detector; Waters Binary Gradient Module) was performed on a Phenomenex Gemini column (5 μM C18, 150 x 4.6 mm) or a Waters XBridgeTM column (5 μM C18, 150 x 19 mm). **General procedure A: Sulfonamide coupling**

![Heteroaryl—Br](image)

**Step 1:** A glass vial was charged with corresponding bromo-heteroaryl compound (0.20 mmol, 1 eq), potassium metabisulfite (88 mg, 0.40 mmol, 2 eq), tetrabutylammonium bromide (70 mg, 0.22 mmol, 1.1 eq), sodium formate (15 mg, 0.22 mmol, 1.1 eq), palladium(II) acetate (5 mg, 0.02 mmol, 0.1 eq), triphenylphosphine (16 mg, 0.06 mmol, 0.3 eq), 1,10-phenanthroline (11 mg, 0.06 mmol, 0.3 eq). After sealing, the vial was flushed with argon for 30 min and the reagents were suspended in dry, degassed DMSO (1 mL) and the reaction mixture was stirred for 4 h at 70°C. After cooling to RT, N,N-Diisopropylethylamine (70 μL, 0.40 mmol, 2 eq) and a solution of tert-butyl (E)-(2-aminoethyl)(3-(4-(pyridin-3-yl)phenyl)allyl)carbamate (63) (106 mg, 0.30 mmol, 1.5 eq) in dry THF (1 mL) were added and the reaction mixture was cooled to 0°C. Subsequently a solution of N-bromosuccinimide (62 mg, 0.40 mmol, 2 eq) in dry THF (1 mL) was added and the reaction mixture was allowed to come to RT. After stirring for 1 h the reaction was quenched by adding H$_2$O (1 mL) and brine (2 mL). The resulting mixture was extracted with EtOAc. The combined organic layers were dried over Na$_2$SO$_4$, filtered and the solvent removed under reduced pressure. The residue was purified via flash-column-chromatography (SiO$_2$, 0% → 5% MeOH in DCM) to yield the desired Boc-protected product, which was used directly in step 2.
**Step 2:** The Boc-protected product was dissolved in chloroform (1.6 mL) and cooled to 0°C. After drop-wise addition of TFA (0.4 mL), the reaction mixture was allowed to come to RT and stirred for 1 h. Chloroform (10 mL) was added to the reaction mixture and subsequently concentrated in vacuum. After co-evaporating with chloroform (1x10 mL), the residue was purified by reverse phase HPLC.

**General procedure B: Suzuki Coupling**

A glass vial was charged with the corresponding bromo-heteroaryl compound (0.15 mmol, 1.5 eq), \( N\)-(2-(isoquinoline-5-sulfonamido)ethyl)3-(4-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)phenyl)propanamide (107) (51 mg, 0.10 mmol, 1 eq) and Pd(PPh\(_3\))\(_4\) (6 mg, 0.005 mmol, 0.05 eq). The vial was put under an argon atmosphere and degassed DMF (0.35 mL) and 2 M degassed aqueous K\(_2\)CO\(_3\) (0.125 mL, 0.25 mmol, 2.5 eq) were added. The reaction mixture was stirred at 85°C overnight, diluted with DCM (10 mL) and half-saturated aq. NaHCO\(_3\) solution (10 mL), extracted with DCM (3x10 mL), dried over MgSO\(_4\), filtered and concentrated under reduced pressure. The residue was purified by reverse phase HPLC.

**General procedure C: Sulfonamide formation**

3-(4-(1H-pyrrolo[2,3-b]pyridin-5-yl)phenyl)-N-(2-aminoethyl)propanamide (113) (50 mg, 0.16 mmol, 1.0 eq) and Et\(_3\)N (45 \( \mu \)L, 0.32 mmol, 2.0 eq) were dissolved in DMF (1.6 mL). The reaction mixture was cooled to 0°C and corresponding sulfonylchloride (194.6 \( \mu \)mol, 1.2 eq) dissolved in DCM (1.6 mL) or DMF (1.6 mL) was added. After 15 min the mixture was warmed up to RT and stirred for 5-16 h. The mixture was quenched with saturated aqueous NaHCO\(_3\) (50 mL), the phases were separated and the aqueous layer was extracted with DCM or with a mixture of 10% MeOH in CHCl\(_3\) (3x40 mL). The combined organic layers were washed with brine (1x100 mL), dried over Na\(_2\)SO\(_4\), filtered and concentrated under reduced pressure. The residue was purified via flash column chromatography and preparative HPLC.
General Procedure D: Sulfonamide formation and debocylation

**Step 1:** tert-Butyl (3-(4-(1H-pyrrolo[2,3-b]pyridin-5-yl)phenyl)propyl)(2-aminoethyl)carbamate (117) (90 mg, 228.3 μmol, 1.0 eq) and Et₃N (63 μL, 456.3 μmol, 2.0 eq) were dissolved in DCM (1 mL). The mixture was cooled to 0°C, corresponding sulfonylchloride (0.27 mmol, 1.2 eq) dissolved in DCM (1 mL) was added and the mixture was allowed to warm up and stirred at 30°C until full conversion was confirmed by TLC (4–40 h). The mixture was quenched with saturated aqueous NaHCO₃ (50 mL), the phases were separated and the aqueous layer was extracted with DCM (3x70 mL). The combined organic layers were washed with brine (1x120 mL), dried over Na₂SO₄, filtered and concentrated under reduced pressure. The resulting residue was purified by flash-column-chromatography (SiO₂, dry-loading, 5% → 7% (10% of sat. aqueous NH₃ in MeOH) in DCM) and used in step 2.

**Step 2:** The product from step 1 was dissolved in DCM (1 mL) and subsequently cooled to 0°C. TFA (250 μL) was added dropwise to the solution and warmed to RT and stirred for 19 h. The mixture was diluted with 15 mL CHCl₃ and concentrated under reduced pressure. The resulting crude was purified by flash-column-chromatography and preparative HPLC to yield the desired compound after lyophilisation.

**(E)-N-(2-(3-(4-(Pyridin-3-yl)phenyl)allyl)amino)ethyl)isoquinoline-5-sulfonamide (1)**

A round-bottom-flask was charged with tert-butyl (E)-2-((isoquinoline-5-sulfonamido)ethyl)(3-(4-(pyridin-3-yl)phenyl)allyl)carbamate (64) (610 mg, 1.12 mmol, 1 eq) dissolved in CHCl₃ (50 mL). After cooling the solution to 0°C and dropwise addition of TFA (12.5 mL), it was allowed to warm to RT and stirred for 30 min. The reaction was quenched by slow addition of sat. aqueous Na₂CO₃ solution (70 mL) until a pH of ~12 was reached and the mixture was extracted with DCM (3x50 mL). The combined organic layers were dried over Na₂SO₄, filtered and concentrated under reduced pressure. The residue was purified via flash-column-chromatography (SiO₂, 0% → 15% (10% of sat. aqueous NH₃ in MeOH) in DCM) to yield the desired product (329 mg, 66%). ¹H NMR (400 MHz, methanol-d₄) δ 9.32 (d, J = 0.7 Hz, 1H), 8.80 (dd, J = 2.3, 0.7 Hz, 1H), 8.61 (d, J = 6.2 Hz, 1H), 8.55 (d, J = 6.2 Hz, 1H), 8.50 (dd, J = 4.9, 1.5 Hz, 1H), 8.47 (dd, J = 7.4, 1.2 Hz, 1H), 8.33 (d, J = 8.3 Hz, 1H), 8.11 – 8.06 (m, 1H), 7.81 – 7.74 (m, 1H), 7.62 (d, J = 8.3 Hz, 2H), 7.53 – 7.48 (m, 1H), 7.46 (d, J = 8.3 Hz, 2H), 6.44 (d, J = 15.9 Hz, 1H), 6.17 (dt, J = 15.9, 6.5 Hz, 1H), 3.21 (dd, J = 6.5, 1.1 Hz, 2H), 3.03 (t, J = 6.4 Hz, 2H), 2.60 (t, J = 6.4 Hz, 2H). ¹³C NMR (101 MHz, methanol-d₄) δ 154.33, 148.68, 148.12, 144.87, 138.41, 138.10, 137.49, 136.36, 136.24, 134.88, 134.75, 132.65, 132.60, 130.62, 128.72, 128.25, 128.21, 127.72, 125.49, 119.15, 68.12, 51.73, 43.06.
