Title: Preventing Leprosy: Epidemiological and immunological aspects of chemo- and

immunoprophylaxis in leprosy patients' contacts

Issue Date: 2020-02-04

Stellingen

- BCG vaccination may precipitate clinical signs and symptoms of tuberculoid leprosy in contacts of leprosy patients and is therefore less suitable for post-exposure prophylaxis in leprosy control. (this thesis)
- 2. Individuals with high local reactogenicity after intradermal BCG administration have less risk for the onset of lepromatous leprosy. (this thesis)
- **3.** Antibodies directed aganst the *M. leprae*-specific phenolic glycolipid I (PGL-I) cannot predict the development of clinical leprosy. *(this thesis)*
- Single-dose rifampicin after BCG vaccination does not provide added benefit as postexposure prophylactic strategy in leprosy control. (this thesis)
- 5. Transmission of *M. leprae* is dependent on the social environment of the patient and mainly targets the poorest of the poor.
- A recent period of food shortage is a socio-economic factor associated with clinical manifestations of leprosy disease.
- Field-friendly tests based on a recently developed lateral flow test format (UCP-LFA), which combine humoral and cellular biomarkers, are useful in identifying which contacts are at risk of developing leprosy at an early stage and to target them for intervention.
- 8. Reduction to zero incidence of infectious diseases such as leprosy in a defined geographical area are a result of deliberate efforts to treat the disease, interrupt transmission and establish continued measures to prevent re-establishment of transmission.
- 9. Poverty causes social stigma, which in turn reinforces exclusion and makes it even harder to escape from poverty.
- 10. Many leprosy patients recognize this feeling: "The biggest disease today is not leprosy or tuberculosis, but rather the feeling of being unwanted" (Mother Teresa, 1971).
