Abstract

This study provides a systematic review of literature from India on traditional bullying and victimization among school-going adolescents. A search of bibliographic electronic databases PsycINFO, MEDLINE, ERIC, Web of Science, and PubMed was performed in May 2020. Thirty-seven studies were included in the review. For each study included, the following specifics were examined: (a) methodological characteristics, (b) prevalence estimates of bullying behavior, (c) forms of bullying, (d) risk factors, and (e) consequences of bullying. It was found that bullying happens in India, and some risk factors for bullying and victimization in India are typical to the Indian context. In addition, bullying in India is associated with adverse consequences for both the aggressor and the victim. Many studies on bullying from India should be interpreted cautiously because of problems with data collection processes, instrumentation, and presentation of the findings. Cross-cultural comparisons for prevalence estimates, and longitudinal studies to examine the direction of possible influence between bullying and its correlates need to be conducted, to cater to the large adolescent population of India.

Keywords Bullying · Victimization · India · Systematic review · Adolescent

Bullying is an intentional and repetitive act of physical or psychological aggression, where the aggressor is more powerful than the victim (Olweus 1993). Meta-analytic studies have confirmed the marked prevalence of and risk factors associated with bullying perpetration and victimization among children and adolescents in school (Modecki et al. 2014). In a recent survey conducted in 79 countries with over 300,000 participants, 30% of the adolescent respondents reported that they had been victims of bullying in the past 30 days (Elgar et al. 2015). In India, research on bullying is scarce, certainly in proportion to its population size, as well as socio-cultural diversity (Milfont and Fischer 2010; Smith et al. 2018). The vast adolescent population provides ample opportunity and resources to further our understanding in the field of bullying. The disparities seen in India in terms of socio-cultural factors such as SES, religion, caste, gender, and color, which have been recognized as typical to the Indian context (Panda and Gupta 2004), may aid in breeding an imbalance of power, an

underlying element of bullying (Olweus 1993). Moreover, given the diverse socio-cultural context of India, and its structural incongruence with western cultures (Charak and Koot 2015), literature from western countries may not be generalizable to the Indian population, thus requiring scientific attention to examine the role of these factors specifically in India (Smith et al. 2018).

Through the current review, we aim to provide researchers a notion of challenges that need to be addressed in future studies on bullying and victimization in India. Systematic reviews are of importance, because they closely follow a scientific and step-by-step approach, with an aim of limiting systematic errors or bias, and particularly seek to identify, evaluate, and synthesize all relevant studies to elucidate knowledge and advanced understanding of the topic at hand (Petticrew and Roberts 2008). The present systematic review focuses on traditional bullying and victimization among adolescents in schools in India, highlighting the following specifics: (a) methodological characteristics of included studies, (b) prevalence estimates of bullying behavior, (c) forms of bullying, (d) risk factors, and (e) consequences of bullying. Specifically, we examine the psychometric properties of the instruments adopted in the included studies from India, as well as methodological characteristics including design and data

collection, sample size and sampling procedures of the included studies, and characteristics of bullying behavior distinctive to the Indian context.

Method

Guidelines provided by Arksey and O'Malley (2005) for conducting systematic reviews were followed in the present study. A systematic search of bibliographic electronic databases PsycINFO, MEDLINE, ERIC, Web of Science, and PubMed was performed in May 2020. The following terms formed the basis of the search strategy: “bullying” OR “peer victim*” OR “bullied” OR “bully” OR “school harassment*” OR “ragging” OR “school violence*” AND “India” OR “Indian” OR “Hindi”. No date limit was set for the search. Our search was not limited to published articles; book chapters, dissertations, unpublished articles, and posters were also eligible. A flow diagram of the search results is provided in Fig. 1. Only studies that focused on bullying by peers and the resulting victimization at school were included. Articles on online bullying or cyberbullying were excluded. There were too few studies on cyberbullying in India to provide a meaningful analysis, especially when such an analysis should also deal with recent concerns about cyberbullying studies (e.g.,

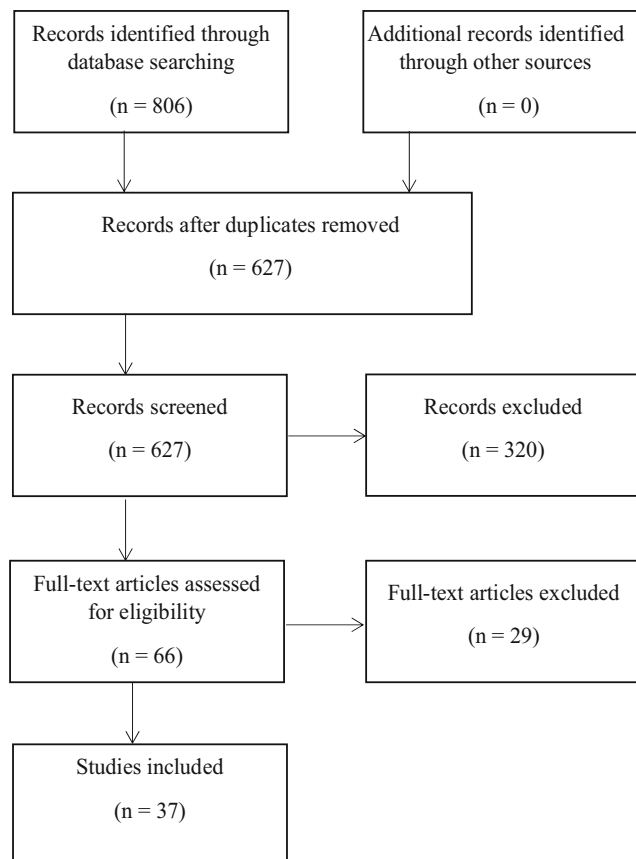

Fig. 1 Search results for the systematic review

Wolke et al. 2017). Non-empirical studies that did not include quantifiable data (for instance, book reviews) were excluded as we focus on only empirical research in the current review. Six studies used interviews to gather data; for instance, Kshirsagar et al. (2007) used Olweus's (1996) pre-tested semi-structure interview to collect data on bullying and victimization in their study. The answers to these interviews were quantified and used in statistical analyses, and therefore, we included the articles in the current review. Studies on Indian children who live outside of India were excluded. Because we focused on adolescents in school, the age of students in included studies should range between 10 and 19 years. For studies on students whose ages only partly overlapped with this intended range, we applied the rule that the average age should fall within the intended range and the lowest and highest age should be within 2 years of the intended age limits. Two studies did not provide a definitive age range of the participants included in their study (Patel et al. 2017; Schäfer et al. 2018); however, the studies indicate that the participants were from grade 8 to 10 (who are typically 12 to 15 years old), thereby qualifying for inclusion in the present review. Three studies did not provide the mean age of the participants in their study though they specify the age range of the participants (Kshirsagar et al. 2007; Malik and Mehta 2016; Ramya and Kulkarni 2011), and because the lower limit or higher limit of the provided age range in these three study fell within 2 years of 11–19 years old, we have included them in the present review. Eventually, 37 studies were included in the final review.

Results

Methodological Characteristics of Included Studies

Design and Data Collection

Of the 37 studies that were included, two were longitudinal studies (Nguyen et al. 2017; Thakkar et al. 2020), two were experimental studies with pre- and post-test intervention designs (Sharma et al. 2020; Shinde et al. 2018, 2020), whereas the others were cross-sectional studies. Seven of the 37 studies used peer-reports, 21 studies used self-reports, two studies used both self- and peer-reports (Chakrabarty and Gupta 2016; Thakkar et al. 2020), whereas six studies used structured or semi-structured interviews and open-ended questions to collect data on bullying and victimization (Kshirsagar et al. 2007; Malhi et al. 2014, 2015; Malik and Mehta 2016; Munni and Malhi 2006; Ramya and Kulkarni 2011). One study used a photo-story method (Skrzypiec et al. 2015), where participants were invited to use a photograph or picture to illustrate their opinions or experiences of bullying.

Psychometric Properties

Psychometric properties of the scales or interviewing approaches used in the studies have been reported in 22 of the 37 studies. Four studies reported the reliability and validity of the original scale (Malik and Mehta 2016; Menon and Hannah-Fisher 2019; Patel et al. 2017; Samanta et al. 2012), but did not report psychometric properties based on the Indian sample, while five studies reported neither the psychometric properties of the original scale nor its generalizability to the Indian sample (Kshirsagar et al. 2007; Maji et al. 2016; Sarkhel et al. 2006; Sharma et al. 2017; Sethi et al. 2019). Two studies used a scale developed by the authors of the study; however, psychometric properties were not reported (Kelly et al. 2016; Prakash et al. 2017). Four studies did not provide a clear description of the method of data collection, and the validity of the approach was not defined (Malhi et al. 2014, 2015; Munni and Malhi 2006; Ramya and Kulkarni 2011). Seven studies specified that the instrument used to assess bullying behavior was an English language questionnaire, while 10 studies used either existing translations or translations created by the authors of the study, of English scales into Indian regional languages. Two studies used English instruments and orally explained the translation in Punjabi (Lee et al. 2018) or translated the difficult words to Hindi (Malik and Mehta 2016), and one study used English and Hindi language translations of the scales (Thakkar et al. 2020).

Sampling

Of the 37 studies, 25 studies used a convenience or purposive sampling approach to recruit participants. One study used a proportionate random sampling approach to recruit participants (Kelly et al. 2016); one study used a two-stage cluster sampling approach (Swain et al. 2014); one used a multi-stage sampling design (Chakrabartty and Gupta 2016); six studies reported using a random sampling method for selecting either schools or participants (Kshirsagar et al. 2007; Maji et al. 2016; Malik and Mehta 2016; Nguyen et al. 2017; Ramya and Kulkarni 2011; Sarkhel et al. 2006), but only one of them reported how the school sample was randomized (by draw of lots; Sethi et al. 2019). Two studies used a randomized control design to allocate participants to experimental or control groups, where Prakash et al. (2017) used a cluster randomized control design, and the intervention study by Shinde et al. (2018) used randomized and masked groups for each of three study groups. One study used a quasi-experimental design, where of the two participating schools, one was randomly assigned to the intervention group, and the other was assigned to the control group (Sharma et al. 2020). Of the 37 studies included in the review, 17 studies had a sample size of less

than 300 participants, nine studies had a sample size of between 300 and 500 participants, whereas 11 studies had a sample size larger than 500 participants.

The articles widely differed in their statistical reporting practices, and therefore, the amount of statistical information provided in the below sections and Table 1 varies per reported study. Time frames of bullying and victimization prevalence estimates are reported in the below sections if they were specified in the included studies. Percentages are rounded off without decimals.

Prevalence Studies

Eight studies focused on the prevalence of bullying in India, while 14 others provided descriptive statistics or percentages for sample participants that qualified as bullies or victims in their study. Of these, five studies provided the participants with a definition of bullying for peer nomination estimates of bullying and victimization in their research (Goossens et al. 2018; Khatri 1996; Lee et al. 2018; Skrzypiec et al. 2018a; Thakkar et al. 2020). Studies from the same city or region in India were scarce, and reports inconsistent. We found that bullying perpetration estimates ranged from 7% (Thakkar et al. 2020) to 31% (Kshirsagar et al. 2007), and bullying victimization ranged from 9% (Thakkar et al. 2020) to 80% (Maji et al. 2016), across studies. For instance, Maji et al. (2016) found that only 38 of 273 adolescents were not bullied, resulting in a dominant 80% students qualifying as victims of bullying. Next to region differences in prevalence, estimates may be related to the reporter used. Kshirsagar et al. (2007) found higher prevalence rates for bullying for self-reports than for parent or guardian interviews, whereas Thakkar et al. (2020) found higher prevalence estimates for bullying and victimization for peer reports than for self-reports. Findings as regards prevalence and other findings or aspects reviewed of each study are reported in Table 1.

Forms of Bullying

It was observed that name-calling or using bad words were common forms of bullying observed among adolescents next to physical bullying. For instance, Kshirsagar et al. (2007) reported that the most common types of bullying were teasing and giving discriminatory or offensive labels and nick names to others. Similarly, Malhi et al. (2014) reported that 16% of their sample were victims of direct bullying or physical bullying and 34% were victims of name-calling. Skrzypiec et al. (2015) showed that caste-based bullying was reported by students and that for females, sexual harassment or “eve-teasing” was a common occurrence.

Table 1 Studies included in the systematic review

Study (year of publication)	City, state	Main variables of the study	Instrumentation	Participants	Bully/victim results	Research findings
1 Bowker et al. (2012)	Surat, Gujarat	Social withdrawal, over and relational aggression, rejection, exclusion, victimization, and gender	Peer nominations	$N = 194$ (48% female); M age = 13.35 years	Overt aggression $M = 0.00$, $SD = 0.90$; relational aggression $M = 0.00$, $SD = 0.86$; rejection $M = 0.00$, $SD = 1.00$; exclusion $M = 0.00$, $SD = 0.90$; victimization $M = 0.60$, $SD = 0.77$ $n = 396$	Overt aggression, relational aggression, and gender were identified as moderators between various associations of social withdrawal and peer victimization
2 Chakrabarty and Gupta (2016)	Kolkata, and Hooghly, West Bengal	Testing validity of translated version of bully scale	Teacher reported each student as bully/non-bully; peer relations questionnaire (Rigby and Slee 1991)	$N = 1147$; M age = 13.06 years, $SD = 1.137$	Identified as bullies by teachers	Factor analysis showed that only one factor was measured by all the response categories implying uni-dimensionality of the bullying scale even if data are collapsed to have various response categories
3 Correia et al. (2009)	Not mentioned	Belief in a just world, school distress in victims, bullies, and defenders, and gender	Peer relations questionnaire (Rigby and Slee 1993)	$N = 278$ Indian sample; 43.9% female; age range = 14 to 17 years, M age = 15.3, $SD = 0.5$	Bully $M = 2.00$, $SD = 0.77$; victim $M = 2.15$; $SD = 0.84$; defender $M = 3.82$, $SD = 0.76$	Higher belief in just world was associated with lower school distress independent of bully status for both genders
4 Donat et al. (2012)	Same Indian sample as above	Belief in a just world, neuroticism, teacher justice, and bullying behavior	Peer relations questionnaire (Rigby and Slee 1993)	Same as above	Bullying behavior $M = 2.00$, $SD = 0.77$	Neuroticism positively correlated with bullying behavior; boys were more likely to perpetrate bullying than girls
5 Goossens et al. (2018)	Patiala, Punjab, and Chidambaram, Tamil Nadu	Bullying, defending, and victimization	Participant role questionnaire (Salmivalli et al. 1996)	Punjab $N = 480$, 69.4% boys; M age = 14.2, $SD = 1.0$; Tamil Nadu $N = 815$ (56.8% boys; M age = 13.6, $SD = 1.1$)	Bully $N = 90$ (7%), 71 boys (9%), 19 girls (4%); defender $N = 75$ (6%), 43 boys (6%), 32 girls (6%); victim $N = 111$ (9%), 90 boys (12%), 21 girls (4%)	Both bullying and defending were linked to dominance in the classroom, but bullies were not preferred, while defenders were. Victims were neither seen as dominant nor were they preferred
6 Gothwal et al. (2013)	Not mentioned	Psychometric properties of Olweus bully/victim questionnaire in visually impaired	Revised Olweus bully/victim questionnaire (Olweus 1996)	$N = 150$, 69% male; M age = 11.6 years, $SD = 2.2$	-	Revised OBVQ is not a valid psychometric instrument to assess victimization and bullying among children with visual impairment
7 Kelly et al. (2016)	5 districts across the state of Rajasthan	Private schooling, caste, income, parental education, school infrastructure, peer bullying, and teacher violence	Peer harassment scale constructed by authors	$N = 413$, 100% females; M age = 18.8 years	Peer harassment in private school $M = 5.88$, $SD = 1.84$; peer harassment in government school $M = 5.49$, $SD = 1.70$; peer harassment in other schools $M = 5.89$, $SD = 1.53$; range = 3 to 15	“General” caste group experienced lower harassment in primary and lower secondary school than their lower caste peers. Parental education, income, or switching schools was not associated with differences in peer bullying

Table 1 (continued)

Study (year of publication)	City, state	Main variables of the study	Instrumentation	Participants	Bully/victim results	Research findings
8 Khatri (1996); Khatri and Kupersmidt (2003) ²	Mandvi, Gujarat	Aggression, victimization, social relationships, caste, grade, and gender	Peer nominations	<i>N</i> = 229, 30% females; grade 4, 6, 8, and 10; one English medium school, one Gujarati medium school	25% males and 10% females qualified as aggressors; 16% males and 0% females qualified as victims; 15% low caste and 8% high caste qualified as rejected; 13% low caste and 6% high caste qualified as victims	Males were significantly more likely to be victims than females; low caste participants were more rejected and victimized than high caste students; no effect of gender or grade on victimization
9 Kshirsagar et al. (2007)	Mumbai, Maharashtra	Bullying prevalence	Olweus's (1996) pre-tested semi-structured interview	<i>N</i> = 500; 188 boys, 312 girls; age range = 8 to 12 years	<i>n</i> = 157 (31% self-reported bullying; forms of bullying reported were teasing (<i>n</i> = 128), keeping names (<i>n</i> = 101), physical hurt (<i>n</i> = 25), use of bad words (<i>n</i> = 53), spreading rumors (<i>n</i> = 9), threatening (<i>n</i> = 8), and isolating others (<i>n</i> = 2); 34% students from English schools and 31% students from vernacular medium (Marathi) schools (<i>p</i> > 0.05) reported bullying; prevalence of bullying higher in co-educational schools than in girls' school	Feeling sad, preferring to stay alone, and frequent tearing of clothes were almost exclusively noted in bullied children; bullied children were more likely to report symptoms such as school phobia, vomiting, and sleep disturbances
10 Lee et al. (2018)	Patiala, Punjab	Risk-taking, and bullying	Participant role questionnaire (Salmivalli et al. 1996)	<i>N</i> = 442 (60% boys); age range = 11.25 to 16.10 years; <i>M</i> age = 13.76, <i>SD</i> = 0.98	Bully <i>M</i> = 0.07, <i>SD</i> = 0.10; follower <i>M</i> = 0.07, <i>SD</i> = 0.09; victim <i>M</i> = 0.08, <i>SD</i> = 0.10; outsider <i>M</i> = 0.04, <i>SD</i> = 0.04; defender <i>M</i> = 0.05, <i>SD</i> = 0.04	Increased risk-taking during adolescence was associated with higher levels of both bullying and victimization; bullying and risk-taking appeared to be more prevalent in India than in the Netherlands
11 Maji et al. (2016)	Ranchi, Jharkhand	Depression anxiety, stress, coping strategies, and bullying	Gatehouse bullying questionnaire (Bond et al. 2007)	<i>N</i> = 273; age range = 10 to 16 years	<i>n</i> = 219 bullied and <i>n</i> = 38 were non-bullied	Bullied participants had higher levels of psychological problems like depression, anxiety, stress, and poor coping strategies like catastrophizing, self-blame, blaming others, and rumination
12 Malhi et al. (2014)	Chandigar, Punjab	Bullying prevalence	Asked 4 questions to assess bullying and victimization	<i>N</i> = 209 (53.4% boys); age range = 13 to 16 years; <i>M</i> age = 14.82, <i>SD</i> = 0.96	Prevalence of bullying = 53%; 13% were bullies, 19% were victims; 16% were victims of direct bullying or physical bullying, 34% victims of name-calling, 13% victims of rumor spreading, and 7%	Victims had low scores on self-concept; bully-victims had higher risk of conduct problems, hyperactivity, and academic difficulties; bullies were better at academics, had high self-esteem, higher risk of hyperactivity, and conduct

Table 1 (continued)

Study (year of publication)	City, state	Main variables of the study	Instrumentation	Participants	Bully/victim results	Research findings
13 Malhi et al. (2015)	Chandigarh, Punjab	Age, gender, SES, bullying, victimization, depression, emotional, and behavioral problems	Questioned students about bullying and victimization	$N = 376$ (53.5% boys); M age = 15.69, $SD = 1.36$	victims of forcibly money taken 24% reported victimization overall; 8% reported physical bullying, 12% relational bullying, 4% victims reported both physical and relational bullying; more physical victimization in boys, more relational victimization in girls ($\chi^2 = 24.15, p = .000$); average duration of physical and relational victimization was 1.24 years ($SD = 1.19$), and 1.17 years ($SD = 1.24$); significant effect of SES on victimization ($\chi^2 = 18.94, p = .001$); significant effect of age between physical and relational victimization ($\chi^2 = 19.74, p = .001$)	problems; boys were more likely to be bully-victims; girls were more likely to be victims Victims of relational aggression were higher on depression and conduct problems; victims of physical aggression were higher on peer problems; low SES participants were higher on physical victimization; high SES participants were higher on relational victimization
14 Malik and Mehta (2016)	Not specified	Bullying, anger, and self-esteem	Peer relations questionnaire (Rigby and Slee 1993); semi-structured interview of some students that were to identified be bullies	$N = 137$; age range = 12 to 14 years	45 students (25 boys) were found to be highly inclined to be bullies; bully $M = 8.91$; victim $M = 9.42$	Boys expressed anger more explicitly than girls; self-esteem of bullies did not differ based on gender
15 Menon and Hannah-Fisher (2019)	Delhi, New Delhi	Felt gender typicality, victimization, aggression, psychosocial adjustment	Reduced aggression/victimization scale (Orpinas and Home 2006)	$N = 296$ (130 girls); M age = 12.73, $SD = 0.84$	Boys reported significantly higher scores than girls on victimization ($\beta = 0.27, p < 0.01$) and aggression ($\beta = 0.33, p < 0.01$). Boys M victimization = 1.54, $SD = 1.63, M$ aggression = 1.16, $SD = 1.44$. Girls M victimization = 0.83, $SD = 1.24, M$ aggression = 0.38, $SD = 0.84$.	For girls, felt pressure and an entity view of gender differences were associated with higher victimization, and work sexism was associated with higher victimization and aggression. For boys, an entity belief of gender differences was associated with higher aggression
16 Munni and Malhi (2006)	Chandigarh, Punjab	Violence exposure, bullying, gender, school performance, and adjustment	Anonymous self-report questionnaire and Interviews	$N = 1500$ (47.4% female); age range = 12 to 20 years, M age = 15 years, $SD = 1.67$; grade 8 to 12	20% students reported bullying others; 8 out of 10 adolescents had witnessed someone being bullied in the past year; girls were significantly more bullied than boys ($p < 0.05$); 60% students engaged in physical fights more than once per week	Significant violence exposure occurs in schools and bullying was also prevalent

Table 1 (continued)

Study (year of publication)	City, state	Main variables of the study	Instrumentation	Participants	Bully/victim results	Research findings
17 Nambiar et al. (2019)	Bengaluru, Karnataka	Peer victimization, self-esteem, intellectual disability	The multi-dimensional peer victimization scale (Mynard and Joseph 2000)	$N = 40$ (15 girls); M age = 14.58 years, $SD = 2.25$; IQ scores between 50 and 85 (mild to borderline intellectual disability)	75% reported the presence of peer victimization ($M = 13.98$, $SD = 12.83$). The highest was verbal victimization (67.5%) with maximum being called names (57.5%), being sworn at (55.0%), being made fun of their appearance (60.0%), or being made fun of them (65.0%). Next was social manipulation (60%) in the form of being refused to be talked to (57.5%) or making others not talk to them (50.0%). Physical victimization (52.5%) was in the form of being hurt physically (50%)	Peer victimization was more common in regular schools compared with special schools. No gender differences in peer victimization. Verbal victimization and social manipulation were significantly related to years of education of student. Self-esteem and peer victimization had a significant negative relationship
18 Narayanan and Betts (2014)	Coimbatore, Tamil Nadu	Bullying, victimization, resilience, and self-efficacy	Adolescent peer relations instrument (Parada 2000)	$N = 393$ (191 males, 202 females); age range = 14 to 20 years; M age = 15.88 years, $SD = 0.64$	Males engaged in significantly greater levels ($p < .001$, $r^2 = .105$), bullying and victimization ($p < .001$, $r^2 = .112$) behaviors compared with females; gender difference in physical bullying: $F(1, 391) = 43.63$, $p < .001$, $r^2 = .105$ (M male = 10.76, $SD = 4.47$; M female = 8.33, $SD = 2.65$); gender difference in physical verbal bullying: $F(1, 391) = 27.43$, $p < .001$, $r^2 = .066$ (M male = 14.52, $SD = 6.20$; M female = 11.59, $SD = 4.83$); gender difference in social bullying: $F(1, 391) = 14.67$, $p < .001$, $r^2 = .036$ (M male = 8.73, $SD = 3.94$; M female = 7.43, $SD = 2.71$)	Resilience mediated the relationship between bullying behaviors and self-efficacy in young men
19 Nguyen et al. (2017)	Andhra Pradesh and Telangana states	Prevalence of bullying victimization, forms of victimization, gender, in urban or rural setting	Social and health assessment peer victimization scale (Ruchkin et al. 2004)	$N = 967$ (49.3% male); M age = 15.0, $SD = 0.3$	M victimization = 13.4, $SD = 4.4$; 56% participants were bullied (boys = 58%; girls = 55%); boys experienced more frequent victimization than girls ($\beta = 4.07$, $p = .002$); urban youth experienced less	Most common victimization was having something forcibly taken while second most common was being punched/kicked/beaten

Table 1 (continued)

Study (year of publication)	City, state	Main variables of the study	Instrumentation	Participants	Bully/victim results	Research findings
20 Nguyen et al. (2019) ³	Same as above	Victimization and psychosocial outcomes	Same as above	Same as above	frequent victimization than rural peers ($\beta = -3.23$, $p = .006$); total model predicted a 1.15 point higher score for boys than girls ($p = .029$) Same as above	At baseline, victimization associated with higher emotional difficulties, and lower subjective well-being. At follow-up, all associations had attenuated and were largely non-significant Victimized girls experienced emotional and sensitive forms of bullying; victimized boys experienced higher physical and verbal bullying; victims were higher on emotional problems, hyperactivity and peer problems
21 Patel et al. (2017)	Vadodra and Anand, Gujarat	Prevalence of bullying, age, gender, height and weight, scholastic performance, and number of friends	Peer interactions in primary school questionnaire (Tarshis and Huffman 2007)	$N = 1106$, from 7th, 8th, and 9th grade	Overall bullying prevalence = 49%; 30 being bullies, and 30% being victims; boys were more likely to be bullies ($p = 0.03$) compared with girls; students having less friends ($p = 0.001$), overweight/obese students ($p = 0.02$), and boys ($p < 0.001$) were more likely to be victims; significant association between bullying behavior and poor academic performance	
22 Prakash et al. (2017)	Bijapur and Bagalkot, Karnataka	School drop-out, absenteeism, and bullying	Questionnaire constructed by authors	$N = 2275$ (100% girls); age range = 11 to 18 years; median age = 13 years	8% ($n = 184$) reported bullying environment	Bullying/harassment at school was associated with increased odds of school dropout and absenteeism
23 Pronk et al. (2017)	Patiala, Punjab	Bullying role behavior and peer group status	Participant role questionnaire (Salmivalli et al. 1996)	$N = 480$ (60.8% boys); M age = 13.8 years, $SD = 12$ months	Bully $M = 0.07$, $SD = 0.10$; follower $M = 0.07$, $SD = 0.09$; victim $M = 0.08$, $SD = 0.10$; outsider $M = 0.04$, $SD = 0.04$; defender $M = 0.05$, $SD = 0.04$	Boys received more nominations for victim and outsider than girls
24 Ramya and Kulkarni (2011)	Davangere, Karnataka	Bullying prevalence, psychological and psychosomatic health	Pre-tested questionnaire used for interviewing by authors	$N = 500$ (336 boys, 164 girls); age range = 8 to 14 years	60% reported being bullied; 53% girls and 64% boys reported being bullied; victimized by boys $n = 220$, by girls: $n = 72$; types of bullying included being called names ($n = 175$; 58%); being made fun of appearance ($n = 47$; 16%); being degraded ($n = 46$; 15%); physical abuse ($n = 38$;	Bullying was seen to be more prevalent among boys than girls; only 65 (39%) parents knew that their children were being bullied; bullied children were more likely to report symptoms such as headache, loose motions, fever, and depression

Table 1 (continued)

Study (year of publication)	City, state	Main variables of the study	Instrumentation	Participants	Bully/victim results	Research findings
25 Samanta et al. (2012)	West Bengal	Prevalence of bullying, protective factors, mental health, and violence	Questionnaire constructed following guidelines of global school-based student health survey (WHO 2001)	$N = 199$ (100% male); age range = 13–15 years; M age urban = 14.1, $SD = 0.87$; M age rural = 15.32, $SD = 0.96$ year	13%); being isolated ($n = 31$; 10%); snatching away things ($n = 29$; 10%); complaining to the teacher ($n = 25$; 8%); spreading rumors ($n = 20$; 7%); blackmailing ($n = 19$; 6%); making fun of one's family ($n = 18$; 6%) Bullying in urban = 46.4%, rural = 17%; fighting in urban = 53.8%, fighting in rural = 26.3%	Mental health- and violence-related issues were prevalent more among urban students than among rural students
26 Sarkhel et al. (2006)	Kanke, Jharkhand	Prevalence of conduct disorder and its subtypes, attention deficit hyperactivity disorder (ADHD), and bullying	Schedule for affective disorders and schizophrenia for school-age children-Present and lifetime version (K-SADS-PL, Kazdin 1996)	$N = 240$; age range = 10 to 15 year old	Bullying M in children with conduct disorder = 2.90, $SD = 0.30$	Lying, bullying, and cruelty to animals were most commonly found symptoms in conduct disorder children
27 Schäfer et al. (2018)	Annamalai Nagar and Pudukchery, Tamil Nadu	Participant roles in pro-bullying behavior and anti-bullying behavior	Participant role questionnaire (Salmivalli et al. 1996)	$N = 911$; grade 8th, 9th, and 10th	Girls nominate boys more on pro-bullying behaviors than on anti-bullying behaviors; boys get significantly more across-gender nominations on pro-bullying behaviors (boys pro-bullying behavior $\mu = 0.53$; $SD = 0.16$; boys anti-bullying behavior $\mu = 0.66$; $SD = 0.16$)/(202.76) = 3.39, $p < 0.01$; $d = 0.40$; for girls, no such difference is found	Both genders nominated primarily within sex; no significant gender difference were found in pro-bullying and anti-bullying behaviors
28 Sethi et al. (2019)	Rohitak, Haryana	Prevalence of school bullying	Korean-peer nomination inventory (Perry et al. 1988)	$N = 370$ (60.5% male); age range = 12 to 15 years	43% of school children were involved in bullying, victims = 19%, perpetrators = 18% and victim-perpetrators = 6%; boys outnumbered girls in all the three categories; 68% ($p < .001$) of the perpetrators belonged to high-income families; fathers of perpetrators were more likely to have completed college than those of non-perpetrators ($p = 0.043$)	Caste and SES contributed to distinguishing students who were involved in bullying behavior from those who were not
29 Sharma et al. (2017)	Delhi, New Delhi	Aggression, school bullying, cyber bullying, and gender	Illinois bully-fight-victim scale (Hamburger et al. 2011)	$N = 174$ (69.5% males); age range = 11 to 15 years	Prevalence of bullies: $n = 27$ (16%), fighting $n = 20$ (11%), victimization $n = 30$ (17%) in the preceding month; males	Being a victim online was comparable with such incidents in-person

Table 1 (continued)

Study (year of publication)	City, state	Main variables of the study	Instrumentation	Participants	Bully/victim results	Research findings
30 Sharma et al. (2020)	Delhi, New Delhi	Pilot evaluation of SETU violence prevention intervention, victimization, physical aggression, nonphysical aggression	Illinois bully fight victim scale (Espelage and Holt 2001)	$N = 95$ (72.5% males) in intervention group, M age = 12.7 years; $N = 108$ (67% male) in comparison group, M age = 12.6 years	were more likely to bully and fight, and be victimized than females At baseline, girls were less likely to endorse aggression and victimization (t values from 3.0–5.1; $p < 0.01$). Victimization score at baseline: intervention school $M = 4.4$, $SD = 3.4$, control school $M = 4.1$, $SD = 3.3$. Nonphysical aggression score at baseline: intervention school $M = 5.2$, $SD = 4.9$, control school $M = 4.6$, $SD = 4.7$. Physical aggression score at baseline: intervention school $M = 3.9$, $SD = 3.4$, control school $M = 3.8$, $SD = 3.2$	At the 6-month follow-up, there was a significant decrease in frequency of nonphysical and physical aggression and victimization. Participants' age and gender moderated effect of intervention on physical aggression. Girls showed greater change in physical aggression compared with boys. The intervention was more effective for older age group (13–14 years old) than younger age group (11–12 years old)
31 Shinde et al. (2018); Shinde et al. (2020) ⁴	Nalanda District, Bihar	School climate, health outcomes, SEHER multi-component intervention	Beyond blue school climate questionnaire (BBSCQ); Sawyer et al. 2010; Bullying Victimization questionnaire (Bond et al. 2007)	Group 1 $N = 4524$ (49% boys); group 2 $N = 4046$ (54% boys); group 3 $N = 4465$ (56% boys); age range = 13 to 18 years	Bullying M : group 1 = 0.75, $SD = 1.5$; group 2 = 0.85, $SD = 1.6$; group 3 = 0.69, $SD = 1.4$; victimization in past 12 months: group 1 $n = 723$ (16%); group 2 $n = 740$, (18%); group 3 $n = 772$ (17%); violence perpetration in 12 months: group 1 $n = 579$ (13%); group 2 $n = 610$ (18%); group 3 $n = 575$ (13%); 37% males ($n = 7$ of 19) and 21% females ($n = 3$ of 14) reported bullying victimization; 84% of reported victims reported male perpetrators; $n = 4$ reported bullying victimization; $n = 13$ reports incidents of physical harassment	SEHER intervention had substantial beneficial effects on school climate and health-related outcomes when delivered by lay counselors, but had no effects when delivered by teachers. At 17-month follow-up, SEHER intervention effects were greatest for frequency of bullying, violence victimization; and violence perpetration (Shinde et al. 2020) Reports of teasing using one's family name (caste-based bullying) was commonly reported by some students; For females, sexual harassment or "eve-teasing" was a common occurrence
32 Skrzypiec et al. (2015)	Patiala, Punjab	Nature of bullying by using photo-story method	Photo-stories	$N = 33$ (57.6% males); Age range = 12 to 15 years, M age = 13.7 years	53% victims of bullying in the preceding 3 months; 36% victims of repeated aggression; 0.2% victims of singular intentional harm; 1% victims of unintentional	Peer aggression experiences that did not meet the bullying criteria were also rated as harmful by victims
33 Skrzypiec et al. (2018a)	South Eastern Punjab	Bullying, peer aggression, and harm perceived by intent, perceived harm, repetition, and power imbalance	Student aggression and victimization questionnaire (SAVQ; Skrzypiec et al. 2015)	$N = 531$ (11.3% females); age range = 11 to 16 years		

Table 1 (continued)

Study (year of publication)	City, state	Main variables of the study	Instrumentation	Participants	Bully/victim results	Research findings
34 Skrzypiec et al. (2018b)	Patiala, Punjab	Bullying, peer aggression- assessed by level of harm, intention, repetition, and power imbalance	Olweus bullying questionnaire (Olweus 1978); peer relations questionnaire (Rigby and Slee 1991)	$N = 186$ (58.6% male); age range = 11 to 15 years; M age = 13.38, $SD = 0.91$	harm; 0.2% not maltreated; 10% children intentionally harmed through peer aggression; 91% reported being harmed from negative experiences with peers 59% reported some level of bullying; 43% classified as having been seriously bullied in the previous month; 17% mildly bullied; 41% never bullied; no gender difference ($\chi^2(2) = 3.85, p > 0.05$, Cramer's $V = 0.15$); students who reported being seriously bullied had the highest victimization scores ($F(2) = 9.7, p < 0.0001$) and ($\chi^2(2) = 15.8, p < 0.0001$); $n = 45$ (24.19%) students who indicated that they had experienced five or more different acts of victimization reported that they had "never" been bullied in the previous month	While peer aggression may be normative, bullying was experienced by a much smaller proportion of students than self-reports indicate; there is confusion about the meaning of "being bullied"
35 Suresh and Tipandjan (2012)	Puducherry, Tamil Nadu	Retrospective bullying in school, and college adjustment	Retrospective bullying questionnaire (Schäfer et al. 2004)	$N = 95$ (62 males)	No significant difference between gender in perceived seriousness of physical bullying during school	Victims of primary school had academic, interpersonal, and self-esteem problems; victims of secondary school had interpersonal, self-esteem, and family problems; victims of both had all three problems. Thus, victimization in school associated with adjustment during college
36 Swain et al. (2014)	Udupi, Karnataka	Traffic rules, violence at school, and suicidal thoughts	Youth risk behavior survey (Centers for Disease Control and Prevention 2013)	$N = 381$ (46.98% females); age range = 15 to 19 years	18% bullied others in the past month at the school campus; 30% were victims in the past 6 months; 11% were involved in serious fights; 10% had been slapped intentionally (14% boys); 19% of students' property had been stolen or damaged by other students in school; $n = 52$ boys bullied someone compared with $n = 18$ girls bullying someone	Boys, students of 16 years of age, affected or victimized by violent activities at school and bullied by were determining factors for violence-related behaviors after adjusting for other variables

Table 1 (continued)

Study (year of publication)	City, state	Main variables of the study	Instrumentation	Participants	Bully/victim results	Research findings
37 Thakkar et al. (2020)	Indore, Madhya Pradesh	Bullying, victimization, psychopathy	Illinois bully fight victim scale (Espelage and Holt 2001); Dyadic peer nominations (Veenstra et al. 2007)	N = 1120 (296 girls) at T1, N = 1036 (274 girls) at T2, N = 1006 (282 girls) at T3; M age = 13 years	Bullies on self-reported scale: 6.3%, 7.6%, and 7.7% at T1, T2, and T3; victims on self-reported scale: 10.3%, 9%, and 8.6% at T1, T2, and T3; bully-victims on self-reported scale: 5.6%, 5.0%, and 6.2% at T1, T2, and T3; bullies on peer-reported scale: 10.8%, 10.3%, and 15.1% at T1, T2, and T3; victims on peer-reported scale: 10.3%, 17.6%, and 12.8% at T1, T2, and T3; bully-victims on self-reported scale: 2.9%, 2.7%, and 2.8% at T1, T2, and T3.	Gender predicted bullies at T2 and bully-victims at T3 for the self-reported scale, where more boys classified as bullies and bully-victims than girls. More general caste students qualified as victims compared with non-general caste. Religion predicted victims at T1 and for the peer-reported scale, where non-Hindu children were significantly more likely to classify as victims than Hindu children. Psychopathic traits, when considered together, predicted bullying behavior in urban, school-going youth

iStudy 3 (Correia et al. 2009) and 4 (Donat et al. 2012) have the same Indian sample in their studies. However, the variables examining correlates and consequences of bullying are different in the studies, and thus for the purpose of our review, we include both studies. iStudy 8 by Khatri and Kupersmidt (2003) is based on a dissertation thesis submitted to University of North Carolina by the first author in 1996. For the purpose of our review, we consider the dissertation and the journal article as one inclusion since the participants as well as bullying reports are the same for both. iStudy 19 (Nguyen et al. 2017) and 20 (Nguyen et al. 2019) have the same Indian sample in their studies. However, the former paper focuses on prevalence and forms of bullying and victimization, whereas the latter one examines psychosocial outcomes of victimization, and thus, we include both studies separately in the present review. iStudy 32 includes reports from two articles (Shinde et al. 2018, 2020). The studies use an intervention design with the same sample, and include reports after 12-month follow-up and 17-month follow-up of the design, both of which have been reported in point 32 in the present review. v Study 35 (Suresh and Tipandjan 2012) uses a retrospective bullying questionnaire with undergraduate college students. As the study focuses on bullying behavior in school retrospectively with adolescents, we included the study in the present review.

Risk Factors for Bullying and Victimization

Thirteen studies from India focus on the risk factors and correlates of bullying and victimization. Risk factors refer to variables that have the potential to increase or decrease the likelihood of bullying behaviors occurring (Olweus 1996), whereas correlates of bullying behaviors focus on factors that are significantly associated with, and co-occur with, bullying behaviors. Risk factors for bullying and victimization identified through the review were body weight (Patel et al. 2017), religion (Thakkar et al. 2020), and age (Malhi et al. 2015; Ramya and Kulkarni 2011), and factors that were found to be significantly correlated to bullying behaviors were personality traits (neuroticism; Donat et al. 2012), academic performance (Patel et al. 2017), urban/rural setting (Nguyen et al. 2017; Samanta et al. 2012), and father's education level (Sethi et al. 2019). Factors that were found to be risks or correlates of bullying behavior in various studies included in the review were caste-system of India (Kelly et al. 2016; Sethi et al. 2019; Thakkar et al. 2020), socio-economic status (Malhi et al. 2015; Sethi et al. 2019), and gender differences.

Studies focusing on the caste system of India reported contradictory findings ranging from “General” caste students experiencing lower harassment (Kelly et al. 2016), “General” caste students experiencing more victimization (Thakkar et al. 2020), to no differences between castes (Khatri 1996). As regards the role of religion, Thakkar et al. (2020) reported that non-Hindu children were significantly more likely to classify as victims than Hindu children. For SES, Malhi et al. (2015) found a significant relationship between SES and victimization, with low SES students scoring higher on physical victimization, whereas high SES students scored higher on relational victimization. For gender comparison, although not fully consistent, most studies within India reported that boys scored higher than girls on bullying perpetration and bullying victimization (Narayanan and Betts 2014; Nguyen et al. 2017; Patel et al. 2017; Pronk et al. 2017; Ramya and Kulkarni 2011; Sethi et al. 2019; Sharma et al. 2017; Swain et al. 2014). Age was also found to have some, though inconsistent, relationship with bullying behavior in school (Malhi et al. 2015; Patel et al. 2017; Ramya and Kulkarni 2011).

Consequences of Bullying

Being bullied was found to be associated with anxiety, depression, and preferring to stay alone (Kshirsagar et al. 2007). Also, bullied children were more likely to report symptoms such as school phobia, vomiting, catastrophizing, self-blaming, and sleep disturbances (Kshirsagar et al. 2007; Maji et al. 2016). Bully-victims had higher risk of conduct problems, hyperactivity, and academic difficulties, and while bullies were found to be better at academics, they had high self-

esteem, and higher risk of hyperactivity and conduct problems (Malhi et al. 2014; Sarkhel et al. 2006).

Discussion

Based on the syntheses of studies included in our review, we draw the following conclusions: (a) limitations in methodological characteristics of studies were identified with regard to sampling, instrumentation, data collection processes, and presentation of findings, and thus, conclusions from the included studies must be considered cautiously; (b) bullying happens in India, as it does internationally, though the range of prevalence estimates varies widely across studies; (c) name-calling, using bad words and other forms of relational and social bullying are common in India, and physical bullying is also prevalent; (d) risk factors for bullying and victimization in India show some factors that are typical to the Indian context, for example, caste; and (e) bullying is associated with adverse consequences for both, the aggressor and the victim, in India.

The current review notes that bullying is widely spread in India. However, available prevalence estimates vary largely across India, for bullying perpetration and for victimization. India is a geographically vast country, with enormous differences in regional socio-demographics (Charak and Koot 2015), thereby constraining prevalence estimates to stratified regions. Scholars have noted that homogeneity within culture in India, like in many other countries, cannot be assumed (Panda and Gupta 2004). Thus, generalizing regional prevalence estimates to be representative across India is questionable, calling attention to the need to conduct cross-regional and cross-cultural comparative studies of bullying behavior within the country.

Furthermore, the type of instruments and their psychometric properties impact the findings of a study (Milfont and Fischer 2010), thereby not only making prevalence estimates from studies in the present review questionable but also warranting caution to conclusions. Also, conclusions about similarities or differences between the Indian and Western contexts require that metric invariance first be established to allow cross-ethnic and cross-cultural comparisons (Milfont and Fischer 2010). Of the 37 studies included in the present review, 22 studies provided descriptions of the psychometric properties of the instruments used, while 15 studies did not report the properties of instruments in their study raising concerns about comparability across studies in terms of instruments used. Furthermore, most studies on bullying in India adopted a quantitative method of data collection, where only 6 out of the included 37 in the present review used a qualitative approach to collect data for their research. The concerns about validity are increased by the over reliance on self-reports; we found that only 7 of the 37 studies used peer-reports, and 2 studies used self- as well as informant reports. In self-rating

procedures, pupils tend to underestimate their aggressive behavior and emphasize prosocial behavior on account of social desirability (Salmivalli et al. 1996). There is an urgent need to validate and standardize instruments, with special attention to peer reports that assess bullying behaviors and establish their generalizability to Indian samples, to attain unbiased reports of bullying behavior in India (Sousa and Rojjanasirat 2011).

Furthermore, only few studies included a sample that is sizable enough to provide firm, stable conclusions (Naing et al. 2006), and thus, the basis for the generalizability of the reports on the prevalence is very narrow. Ioannidis (2005) asserted that the smaller the sample sizes in a study, the smaller the power of the study, and consequently the higher the likelihood of the research findings to be affected by bias. Thus, we emphasize the need to conduct more studies across India, with proportional sample sizes for objective, less biased conclusions regarding bullying behavior. Also, the purposive selection of participants in 25 of the 37 included studies poses a potential threat to the validity of findings. In future studies, random sampling approaches should be used to study bullying in India.

Furthermore, we observe that there are only two longitudinal studies from India (Nguyen et al. 2019; Thakkar et al. 2020). Longitudinal studies help disentangle antecedents and consequents, to estimate the inter-individual variability in intra-individual (or within-person) patterns of change (Curran et al. 2010), allowing investigations of the sequence of occurrence of bullying with its risks and outcomes. Additionally, several studies in the present review report the adverse effects of bullying; however, the magnitude of these effects remains unclear. Only two of the 37 included studies were experimental studies with pre- and post-test intervention designs (Sharma et al. 2020; Shinde et al. 2018, 2020), which also underlines the urgent need to conduct fundamental indigenous research on the topic of bullying behaviors so that future research focusing on effective and tailor-cut interventions can be modeled for the Indian context. Also, given that most studies included were cross-sectional, cause and effect reasoning for bullying behavior remains elusive in India, and warrants further attention.

Lastly, we emphasize that risk factors of bullying need to be studied in light of the Indian culture to understand its meaning and relevance in the culture (Smith et al. 2018). In western literature as well, several recent studies have indicated a growing need to study bullying in relation to its broader socio-cultural context (Graham 2016). This is imperative in the Indian context given the contextual-development perspective (Chen and French 2008), which suggests that in collectivistic countries like India, context is more likely to affect evaluations of socially acceptable behavior and experiences, rather than individual attributes. Given the diversity and population density of India, considerable disparities and inequalities coexist between cultures and also within the sub-groups of

particular cultures (Panda and Gupta 2004). For instance, factors such as caste, dissimilarities between urban and rural youth, and the range of SES as observed in India can help in better, more deeply understanding bullying.

Conclusions and Implications for Future Research

This review contributes valuable findings in the field of bullying and victimization in India. However, it has been noted that conducting research in India comes with its own set of logistical and contextual challenges (Smith et al. 2018), and thus, the conclusions drawn through the review must be considered with due caution given methodological limitations of the included studies. The quality of research conducted in India has scope of improvement in terms of methodological rigor, data collection processes, instrumentation, and presentation of the findings.

The present study is limited in capacity as it does not include a report on cyberbullying, and thus, future research on the topic of cyberbullying is necessitated within the Indian context. Furthermore, terms such as “aggression” and “discrimination” were not used as search terms in the current study. However, bullying is a form of aggression, and discrimination could be, in some cases, strongly tied to bullying (Verkuyten and Thijs 2002). Future studies should pay more attention to the relations between bullying and discrimination.

In contrast to the large body of research on bullying from western countries where findings have been reproduced with a delimited adolescent population insistently, data from India is scanty. India accommodates the largest adolescent population in the world, providing a potential reservoir of relatively untapped resources that could provide in-depth knowledge of causes and consequences of bullying and victimization. Given its special cultural context, there is considerable scope to scrutinize cultural contexts of bullying behavior in India that could assist in revealing novel insights, such as the role of socio-economic distance between different sects of society in low to middle income countries. Such insights might facilitate the conception of dynamic intervention designs for not only the Indian population but also for western populations. Future studies that compare how bullying happens in the western and Indian context would also help shed further light on this topic.

Notes

1. Study 3 (Correia et al. 2009) and 4 (Donat et al. 2012) have the same Indian sample in their studies. However, the variables examining correlates and consequences of

bullying are different in the studies, and thus for the purpose of our review, we include both studies.

2. Study 8 by Khatri and Kupersmidt (2003) is based on a dissertation thesis submitted to University of North Carolina by the first author in 1996. For the purpose of our review, we consider the dissertation and the journal article as one inclusion since the participants as well as bullying reports are the same for both.
3. Study 19 (Nguyen et al. 2017) and 20 (Nguyen et al. 2019) have the same Indian sample in their studies. However, the former paper focuses on prevalence and forms of bullying and victimization, whereas the latter one examines psychosocial outcomes of victimization, and thus, we include both studies separately in the present review.
4. Study 32 includes reports from two articles (Shinde et al. 2018; Shinde et al. 2020). The studies use an intervention design with the same sample, and include reports after 12-month follow-up and 17-month follow-up of the design, both of which have been reported in point 32 in the present review.
5. Study 35 (Suresh and Tipandjan 2012) uses a retrospective bullying questionnaire with undergraduate college students. As the study focuses on bullying behavior in school retrospectively with adolescents, we included the study in the present review.
