The Fundamental Plane

Redshift evolution of the FP traces the evolution in M/L

Bezanson+ 2013

LEGA-C Survey

- ❖ Measuring kinematics at high redshifts is challenging
 - ❖ LEGA-C: Deep spectroscopic survey of massive galaxies with VIMOS
(van der Wel+ 2016, Straatman+ 2018)
 - ❖ ~3000 K-band selected galaxies at intermediate redshifts ($0.6 < z < 1.0$)
 - Factor ~10 improvement in sample size!
- + great wealth of ancillary data (galaxy morphologies, multi-wavelength photometry)

Redshift evolution?

Summary/prospects

- Massive galaxies lie on the same mass fundamental plane across 7 Gyr of cosmic time, despite large variation in their properties
- Progenitors and descendants lie on the same scaling relation:
Evolution in the morphology and stellar kinematics of galaxies must be tightly coupled
- We can use the mass fundamental plane as a tool to track the structural evolution of massive galaxies across time
