## Synthesis of glycosylated ribitol phosphates and their binding to human langerin

## INTRODUCTION

The skin provides the first line of defense against microbes and the skin immune system relies on a rich network of professional antigen-presenting dendritic cells (DCs) on the epidermis and dermis. ${ }^{1-2}$ Langerhans cells (LCs) are a subset of DCs, present in the epidermis and they express high levels of langerin, a CD207 C-type lectin receptor ${ }^{3}$, which aids in the detection of invading pathogens by binding to pathogen-associated molecular patterns (PAMPs). Langerin is involved in the detection and uptake of a wide set of pathogens, including viruses like $\mathrm{HIV}^{4}$ and measles ${ }^{5}$, fungi ${ }^{6}$, and (myco)bacteria. ${ }^{7}$ Langerin is a type II C-type lectin receptor that has been shown to bind mannose, fucose, glucose, galactose-6-phosphate as well as N -acetyl glucosamine and sulfated heparin disaccharides, in a calcium dependent manner through its carbohydrate-recognition domain. ${ }^{8}$

[^0]Staphylococcus aureus (S. aureus) is a commensal bacterium residing on our skin and LCs play a crucial role in the host defence against the bacterium. The cell wall of $S$. aureus is densely functionalized with wall teichoic acids (WTAs), ribitol phosphate (RboP) polymers decorated with N -acetyl glucosamine (GIcNAc) and D-alanine residues. As described in Chapter 1 and 2, WTAs are involved in host interaction, biofilm formation, cation homeostasis and autolysin activity. It has previously been shown that langerin can recognize $\beta$-GlcNAc modifications on S. aureus contributing to LC activation and production of Th1- and Th17-polarizing cytokines, while $\alpha$-GlcNAcylation was found to impair langerin interaction, weakening the functional response of LCs. ${ }^{9}$ This latter finding implies that $S$. aureus can modulate immune detection and subsequent inflammation in the epidermis. van Dalen et al. ${ }^{9}$ reported langerin as the first human innate receptor to discriminate between the $\alpha$-GlcNAc and $\beta$-GlcNAc modifications. Unraveling the interactions of $S$. aureus WTAs and langerin at the molecular level is of importance for the development of a vaccine specifically targeting skin and soft tissue infections and may also open up possibilities for the targeted delivery of vaccines. ${ }^{10-11}$

Since the isolation of WTA from bacterial sources results in heterogenous fragments with possible bacterial contaminations, the synthesis of well-defined fragments is of great interest. This Chapter describes the synthesis of a set of glycosylated ribitol phosphate oligomers, varying in length of the ribitol phosphate chain as well as the substitution pattern. Both C-4- $\alpha$ - and C-4- $\beta-$ GIcNAc are incorporated (Fig 1). The GIcNAc-WTAs fragments will be equipped with an aminohexanol linker that serves as a ligation handle to attach the molecules to surfaces, biotin affinity handles or carrier proteins for example. The short trimer fragments are intended for future crystallization studies. These latter fragments lack the flexible spacer entity as its presence may hamper crystallization.

## RESULTS AND DISCUSSION

As discussed in Chapter 1, a team at Sanof Pasteur synthesized two octamers with either an $\alpha$ - or a $\beta$-GIcNAc on the C-4 of each ribitol phosphate moiety and a nonamer bearing a C-3 $\beta$-GlcNAc on each ribitol phosphate repeating unit using a block coupling
approach. ${ }^{12}$ The spacer was installed in the last coupling event to the ribitol phosphate chain, on the opposite position on the WTA chain with respect to the peptidoglycan binding site. Jung et al. ${ }^{13}$ also used a block approach to generate ribitol phosphate tetramers bearing an $\alpha$ - or $\beta$-GIcNAc moiety at C-4 of the RboP motifs, and D-alanine amides at C-2. This Chapter outlines a strategy for the assembly of well-defined WTA fragments based on repetitive coupling cycles using monomeric RboP building blocks to allow for maximum flexibility in terms of substitution patterns that can be targeted. The spacer will be attached at the site of the WTA chain where the peptidoglycan is attached in the bacterial structures.

Scheme 1 depicts the synthesis of the required phosphoramidite building blocks 20, 37, and 41 , which will be used alongside building block 42 (Scheme 2), the synthesis and use of which has been described in Chapter 2. Scheme 1A shows the synthesis of $\mathrm{C} 4-\mathrm{OH}$ ribitol 12, and starts from compound 9 by allylation of the primary alcohol, followed by isopropylidene hydrolysis to yield $\mathbf{1 0}$. Benzylation and ensuing acidic hydrolysis of the methyl riboside yielded the corresponding hemi-acetal intermediate and subsequent ring opening using sodium borohydride provided primary alcohol 11. Protection with a TBDPS group then gave acceptor 12. Two approaches were explored to introduce the $\beta$-GlcNAc as shown in scheme 1B. In the first approach, acceptor 12 was coupled with trichloroacetimidate donor 14. The TCA protecting group on the glucosamine donor can participate in the stabilization of the oxocarbenium ion formed upon activation of the donor, forcing the nucleophilic attack to the other side of the pyranose ring leading to the desired $\beta$-product and coupling of acceptor 12 and donor 14 afforded the desired $\beta$-product 15 in $92 \%$ yield. Subsequent deacetylation under Zemplén conditions yielded triol 16, after which the alcohols were benzylated. To avoid benzylation of the trichloroacetamide the reaction was kept at $0^{\circ} \mathrm{C}$ although this also led to slower and incomplete conversion of the starting material. The TCA was removed using $\mathrm{CsCO}_{3}$ in DMF at $70^{\circ} \mathrm{C},{ }^{14}$ followed by acetylation of the free amine and TBAF mediated TBDPS removal to yield $\beta$-product $\mathbf{1 7}$ in $42 \%$ over 4 steps. The primary alcohol was protected with a DMTr group in $53 \%$ yield, after which an iridium catalyzed allyl isomerization and iodine mediated enol ether hydrolysis delivered alcohol 19 in 79\%. Equipment of the alcohol with a cyanoethyl protected phosphoramidite yielded key building block 20 for the upcoming oligomerization. Although the TCA protecting group served well to provide a $\beta$-selective glycosylation reaction, its undesired reactivity in the benzylation reaction and relatively difficult removal made the assembly of $\mathbf{2 0}$ using donor $\mathbf{1 4}$ suboptimal. To circumvent the use of a TCA group, a second route was developed in which glucose azide $\mathbf{2 6}$ was coupled to acceptor 12. This donor ${ }^{15}$ was synthesized starting from commercially available glucosamine 21, of which the amine was masked with an azide using Stick's reagent ${ }^{16}$ after which acetylation gave 22. Subsequent introduction of a
thiophenol and deacetylation under Zemplén conditions led to compound 23 in 56\% over 2 steps. Benzylation of the free alcohols gave $\mathbf{2 4}$ in $98 \%$ yield and hydrolysis of the anomeric thiophenyl gave hemiacetal 25 in $62 \%$ yield. The hemiacetal was equipped with an imidate moiety, completing the synthesis of donor $\mathbf{2 6}$. The use of acetonitrile as a $\beta$-directing solvent in combination with a low reaction temperature ensured the stereoselective formation of the desired $\beta$-glucosamine linkage and $\mathbf{2 7}$ was obtained in $85 \% .^{17-24}$ Propanedithiol mediated azide reduction, followed by acetylation delivered acetamide $\mathbf{2 8}$ in 59\% over 2 steps and removal of the TBDPS afforded alcohol 19 in 68\% yield. Overall this latter route proved significantly more efficient than the route using TCA-donor 14.

The synthesis of amidite 37, bearing the $\alpha$-GlcNAc appendage is shown in Scheme 1C. Azide donor $\mathbf{2 9}$ was coupled with acceptor $\mathbf{1 2}$ to yield $\mathbf{3 0}$ as a 7:1 $\alpha / \beta$ mixture. The two anomers could be separated after Zemplén deacetylation, leading to the pure $\alpha$ product 31 in $70 \%$ yield. ${ }^{25}$ Benzylation of the liberated alcohols, followed by Staudinger reduction and subsequent acetylation of the amine yielded 33 in $89 \%$ yield over 3 steps. Removal of the TBDPS group gave 34 in $86 \%$ yield and protection of the primary alcohol with a DMTr group afforded $\mathbf{3 5}$. Allyl removal as described above yielded the primary alcohol 36 which was functionalized with a cyanoethyl phosphoramidite to give the second key building block 37 in $81 \%$ yield.

Where the spacer is required for conjugation and biological purposes, it may impede crystallization studies. Therefore, a terminal building block was generated with a benzyl group at the terminating alcohol. To this end phosphoramidite 41 was assembled by benzylation of alcohol $\mathbf{3 8}$ which was followed by detritylation to yield intermediate $\mathbf{4 0}$ in $66 \%$ over 2 steps. Conversion into the amidite yielded 41.

With all the required phosphoramidites in hand, the stage was set to assemble the target library (Fig 1). Scheme 2A schematically depicts the assembly of the fragments. For the elongation of the oligomers, the condensation procedure described in Chapter 2 was employed: in the first step the phosphoramidite is activated by DCI, after which the activated group is replaced by the incoming alcohol of the growing chain to yield the phosphite triester. Subsequent oxidation using CSO affords the phosphate triester, after which a detritylation step using 3\% DCA in DCM liberates the alcohol for the next coupling event. Purification was achieved by size exclusion or silica gel column chromatography.

As described in Chapter 2, alcohol 38 was coupled with spacer phosphoramidite 43 to give monomer 44. Detritylation then set the stage for a second coupling cycle with amidite 42 to deliver dimer 45, which was coupled to $\beta$-GIcNAc amidite $\mathbf{2 0}$ or $\alpha$-GIcNAc amidite 37 to give trimers 46 and 47 . Both trimers were extended by two coupling cycles using $\mathbf{4 2}$ to yield pentamers $\mathbf{5 0}$ and $\mathbf{5 1}$. Both pentamers were coupled to $\mathbf{2 0}$ or $\mathbf{3 7}$ yielding four double glycosylated hexamers $\mathbf{5 2 , 5 3 , 5 4 , 5 5}$ with a different substitution pattern. In addition, unsubstituted pentamer $\mathbf{5 6}$ (Chapter 2) was coupled to amidite $\mathbf{2 0}$ and $\mathbf{3 7}$ to yield hexamers $\mathbf{5 7}$ and $\mathbf{5 8}$ bearing a single terminal GlcNAc moiety. Global deprotection using aqueous ammonia and subsequent hydrogenolysis of the semi protected fragments yielded hexamers $\mathbf{1 , 2 , 3 , 4 , 5}$, and $\mathbf{6}$.

Scheme 2B depicts the generation of the $\alpha$ - and $\beta$-GIcNAc trimers, designed for crystallization studies. Phosphoramidite 41 was coupled to $\alpha$ - and $\beta$-GIcNAc ribitol alcohol 36 and 19 giving dimers 59 and 61, which were coupled with amidite 42 to afford trimers 60 and 62. Global deprotection as described above yielded trimers 7 and 8.

To study the interactions of glycosylated and non-glycosylated WTAs with human langerin, a micro array interaction study was undertaken. As previously reported by van der Es et al., ${ }^{26}$ teichoic acid (TA) micro arrays can be employed to rapidly report on the sequence binding specificity of biomolecules interaction with TAs. Thus, amino spacer functionalized WTA fragments 1-5 as well as non-glycosylated trimer 63, tetramer 64, octamer 65, and dodecamer 66 (Chapter 2) were coupled to epoxide functionalized micro array slides and the generated arrays were interrogated using langerin-FITC. 8, ${ }^{27}$ As can be seen in Figure 2, the WTAs that bear a $\beta$-GlcNAc show selective binding to langerin, with fragment $\mathbf{2}$ having $2 \beta$-GlcNAcs showing highest binding. The $\alpha-G I c N A c$ WTAs $(\mathbf{3}, 4)$ did not bind to langerin, nor did the unsubstituted WTAs (63-66). WTA 5 that bears an $\alpha$ - and a $\beta$-GlcNAc shows binding comparable to the mono- $\beta$-GIcNAc WTA 1. The array clearly reveals that langerin does not bind to the RboP-backbone and that a $\beta$-GlcNAc is required for binding. These results support the data of van Dalen et al. ${ }^{9}$, who studied binding of langerin-FITC to a panel of $S$. aureus strains, expressing either the glycosyltransferase TarM or TarS, responsible for the introduction of WTA$\alpha$ - and WTA- $\beta$-GIcNAc residues, respectively. It was shown that the knock-out of both enzymes ( $\Delta \mathrm{TarS} / \mathrm{TarM}$ ) decreased langerin binding compared to the wild-type indicating that a GlcNAc is required for binding. The $\Delta$ TarM species showed increased binding to langerin compared to the $S$. aureus wild-type, while the $\Delta T a r S$ bacterium showed 7-8 fold lower binding compared to the wild type. These results showed that at the bacterial level the WTA $\beta$-GIcNAc is required for langerin binding and that the $\alpha$-GlcNAc-moieties could hinder langerin binding. The micro array results confirm langerin WTA $\beta$-GIcNAc binding at the molecular level, and show that a single $\alpha$-GlcNAc-residue (as in 5) does

not adversely affect interaction of the C-type lectin with the WTA $\beta$-GIcNAc-moieties. The differences between the $S$. aureus study of van Dalen et al. and the here presented results may be explained by the different number of GlcNAc residues per RboP unit and/ or the difference in density of the WTAs on the array vs the bacterial cell wall. In addition, D-alanine residues may also play a role in WTA-langerin interaction.

Figure 2. A) Human langerin binding on a RboP micro array. X-as represents the WTA fragments printed with 3 different concentrations on the slide; B) WTA fragments included on micro array for their langerin binding.

To further probe langerin WTA binding with fragments having a higher density of GIcNAc residues, an assay using WTA functionalized magnetic beads was employed. Thus, as described in Chapter 2, the biotinylated non-glycosylated RboP-hexamer and RboP-dodecamer were enzymatically glycosylated using the enzymes TarS, TarM and TarP generating $\beta$-( 1,4 )-GIcNAc-WTA, $\alpha-(1,4)$-GIcNAc-WTA and $\beta$-( 1,3 )-GIcNAc-WTA respectively, which were then captured on streptavidin functionalized beads. Figure 3 shows langerin-FITC binding to these beads and reveals that both the $\beta-(1,4)$ - and $\beta$-(1,3)-GlcNAc-WTAs are recognized by langerin, with equal binding efficiency. The dodecamer shows significantly higher binding than the hexamers. Thus, although the microarray has indicated that a single $\beta$-GIcNAc can already provide langerin binding, the presence of more copies of the sugar ligand on the RboP chains leads to stronger binding with the lectin.

## CONCLUSION AND OUTLOOK

This Chapter described the successful synthesis of a set of C-4 glycosylated WTAs on milligram scale. Here, the phosphoramidite chemistry developed in Chapter 2 was further extended by synthesizing $\alpha$ - and $\beta$-linked C4-GIcNAc ribitol phosphoramidite building blocks. The synthetic route towards $\beta$-glycosylated amidites was realized following two approaches with different donors. The trichloroacetamide protecting group, chosen for the excellent beta selectivity during the glycosylation reaction, showed to be less optimal for the overall efficiency in the rest of the route. It presented an obstacle during the benzylation and its removal proved challenging. Meanwhile, the glucose azide donor, bearing a non-participating group on the C-2 gave excellent beta-selectivity in a nitrileassisted glycosylation reaction and no further laborious steps in the synthesis route were encountered, making the approach using this latter donor the preferred one to generate the required building block on multigram scale. The activity of the synthesized WTAs towards langerin has been established on a micro array platform and it was found that langerin binds in selective manner to the $\beta$-epitope. A similar outcome was found using WTA-functionalized beads, carrying TarS, TarM or TarP modified synthetic ribitol phosphate hexa- or dodecamers. The $\alpha$-GIcNAc WTA beads did not capture langerin, while the $\beta$-GIcNAc functionalized beads effectively bound the C-type lectin. The position of the GIcNAc on the ribitol phosphates seems to be of less importance for binding. These results clearly demonstrate $\beta-G l c N A c-W T A$ to be an epitope for human langerin. Establishing the molecular interaction of langerin and S. aureus using well-defined WTA fragments is of great importance for the development of treatments against S. aureus soft skin and tissue infections. The activity of the glycosylated WTA-fragments against monoclonal antibodies will be presented in Chapter 4 to reveal the role of these antigens in adaptive immunity.

## EXPERIMENTAL SECTION

## General information

All chemicals (Acros, Fluka, Merck, Sigma-Aldrich, etc.) were used as received and reactions were carried out dry, under an argon atmosphere, at ambient temperature, unless stated otherwise. Column chromatography was performed on Screening Devices silica gel 60 ( $0.040-0.063 \mathrm{~mm}$ ). TLC analysis was conducted on HPTLC aluminium sheets (Merck, silica gel 60, F245). Compounds were visualized by UV absorption ( 245 nm ), by spraying with $20 \% \mathrm{H}_{2} \mathrm{SO}_{4}$ in ethanol or with a solution of $\left(\mathrm{NH}_{4}\right)_{6} \mathrm{Mo}_{7} \mathrm{O}_{24} \cdot 4 \mathrm{H}_{2} \mathrm{O} 25 \mathrm{~g} / \mathrm{L}$ and $\left(\mathrm{NH}_{4}\right)_{4} \mathrm{Ce}\left(\mathrm{SO}_{4}\right)_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O} 10 \mathrm{~g} / \mathrm{L}$, in $10 \%$ aqueous $\mathrm{H}_{2} \mathrm{SO}_{4}$ followed by charring at $+/-140^{\circ} \mathrm{C}$. Some unsaturated compounds were visualized by spraying with a solution of $\mathrm{KMnO}_{4}$ (2\%) and $\mathrm{K}_{2} \mathrm{CO}_{3}(1 \%)$ in water. Optical rotation measurements ( $[\alpha]_{D}{ }^{20}$ ) were performed on an Anton Paar Modular Circular Polarimeter MCP 100/150 with a concentration of $10 \mathrm{mg} / \mathrm{mL}$ ( c 1), unless stated otherwise. Infrared spectra were recorded on a Shimadzu FT-IR 8300. ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and ${ }^{31} \mathrm{P}$ NMR spectra were recorded with a Bruker AV 400 (400, 101 and 162 MHz respectively), a Bruker AV 500 ( 500 and 202 MHz respectively) or a Bruker DMX 600 ( 600 and 151 MHz respectively). NMR spectra were recorded in $\mathrm{CDCl}_{3}$ with chemical shift ( $\delta$ ) relative to tetramethylsilane, unless stated otherwise. High resolution mass spectra were recorded by direct injection ( $2 \mu \mathrm{l}$ of a $2 \mu \mathrm{M}$ solution in water/acetonitrile; 50/50; v/v and 0.1 \% formic acid) on a mass spectrometer (Thermo Finnigan LTQ Orbitrap) equipped with an electrospray ion source in positive mode (source voltage 3.5 kV , sheath gas flow 10 , capillary temperature $250^{\circ} \mathrm{C}$ ) with resolution $\mathrm{R}=60000$ at $\mathrm{m} / \mathrm{z}$ 400 (mass range $m / z=150-2000$ ) and dioctylphthalate ( $m / z=391.28428$ ) as a lock mass. The high resolution mass spectrometer was calibrated prior to measurements with a calibration mixture (Thermo Finnigan).

## Phosphoramidite coupling, oxidation, and detritylation

The starting alcohol was co-evaporated 2 times with toluene before being dissolved in acetonitrile (ACN, 0.15 M ). 4,5-dicyanoimidazole (DCI) (1.6-2.4 eq; 0.25 M in ACN) was added and the mixture was stirred over freshly activated molecular sieves under an argon atmosphere for 20 min . Then phosphoramidite (1.3-2.0 eq; 0.20 M ) was added and the mixture was stirred at rt until total conversion of the starting material (15-45 min). Subsequently, (10-camphorsulfonyl)oxaziridine (CSO) ( 2.0 eq; 0.5 M in ACN) was added and the stirring was continued for 15 min . The mixture was diluted with DCM and washed with a $1: 1$ solution of saturated $\mathrm{NaCl} / \mathrm{NaHCO}_{3}$. The water layer was extracted 3 times with DCM and the combined organic layers were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered, and concentrated in vacuo. The crude product was dissolved in DCM, DCA was added (5 eq; 0.18 M in DCM), and the mixture was stirred at rt. After 40-60 min an aqueous solution of methanol (1:1) was added, stirred for an additional 30-40 min, and diluted with DCM.

The organic layer was washed with saturated $\mathrm{NaCl} / \mathrm{NaHCO}_{3}$ solution (1:1), the water layer was extracted 3 times with DCM, and the combined organic layers were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated in vacuo. The crude product was purified by either flash chromatography (DCM/acetone) or size exclusion chromatography (sephadex LH20, MeOH/DCM, 1/1).

## General procedure for global deprotection

The oligomer was dissolved in a 1:1 solution of $\mathrm{NH}_{3}(30-33 \%$ aqueous solution) and dioxane (1.2-2.4 mM) and stirred overnight. The mixture was concentrated in vacuo and loaded on a Dowex $\mathrm{Na}^{+}$cation-exchange resin ( $50 \mathrm{WX} 4-200$, stored on 0.5 M NaOH , flushed with $\mathrm{H}_{2} \mathrm{O}$ and MeOH before use) column and flushed with water/dioxane (1:1). The fractions were then concentrated in vacuo, dissolved in water/dioxane ( 2 ml per 10 $\mu \mathrm{mol}$ ) and 4 drops of glacial AcOH were added. After purging the mixture with argon, Pd black was added ( $32-59 \mathrm{mg}$ ), and the mixture was repurged with $\mathrm{N}_{2}$. The mixture was stirred under hydrogen gas for 3-7 days, filtered over celite, and concentrated in vacuo. The crude product was purified by size-exclusion chromatography (Toyopearl HW-40, $\mathrm{NH}_{4} \mathrm{OAc}$ buffer) and the fractions were concentrated. The product was co-evaporated repeatedly with MilliQ water to remove $\mathrm{NH}_{4} \mathrm{OAc} / \mathrm{NH}_{4} \mathrm{HCO}_{3}$ traces and eluted through a Dowex $\mathrm{Na}^{+}$cation-exchange resin column, and lyophilized.

## Methyl 2,3-O-isopropylidene- $\alpha$-D-ribofuranoside (9)

D-Ribose ( $40.0 \mathrm{~g} ; 266 \mathrm{mmol} ; 1.0 \mathrm{eq}$.) was dissolved in MeOH ( 950 $\mathrm{ml} ; 0.28 \mathrm{M}$ ) and $\mathrm{AcCl}(5.7 \mathrm{ml} ; 0.3 \mathrm{eq}$.) was added and the mixture was stirred for 2 h at rt . Then the mixture was quenched with $\mathrm{Na}_{2} \mathrm{CO}_{3}$, filtrated and concentrated. The crude was dissolved in acetone ( $750 \mathrm{ml}, 0.35 \mathrm{M}$ ), $\mathrm{HCl}(16 \mathrm{ml})$ was added and the mixture was stirred overnight at rt . The mixture was quenched with $\mathrm{Na}_{2} \mathrm{CO}_{3}$, filtrated and concentrated under reduced pressure. Column purification pentane/EtOAc 9:1 to 6:4 pentane/EtOAc afforded the title compound 9 in $72 \%$ over 2 steps ( $39.0 \mathrm{~g} ; 190.9 \mathrm{mmol}$ ). ## 5-O-allyl-2,3-O-benzyl-D-ribitol (11)

Compound 10 ( $24.1 \mathrm{~g} ; 118 \mathrm{mmol} ; 1.0 \mathrm{eq}$.) was co-evaporated twice with toluene before use and was dissolved in a mixture of THF/DMF ( $590 \mathrm{ml} ; 0.30 \mathrm{M} ; \mathrm{v} / \mathrm{v}=7: 1$ ). The solution was cooled to $0^{\circ} \mathrm{C}$ and NaH ( $7.1 \mathrm{~g} ; 177 \mathrm{mmol} ; 1.5 \mathrm{eq}$.) was added, followed by dropwise addition of $\mathrm{BnBr}(21.0 \mathrm{ml}$; $177 \mathrm{mmol} ; 1.5 \mathrm{eq}$.). The remaining $\mathrm{NaH}(7.1 \mathrm{~g} ; 177 \mathrm{mmol} ; 1.5 \mathrm{eq}$.$) was added followed$ by the dropwise addition of $\operatorname{BnBr}$ ( $21.0 \mathrm{ml} ; 177 \mathrm{mmol} ; 1.5 \mathrm{eq}$.) and the mixture was allowed to warm up to rt and was stirred overnight. Then the mixture was quenched with MeOH at $0^{\circ} \mathrm{C}$, diluted with $\mathrm{Et}_{2} \mathrm{O}$ and the organic layer was washed 5 x with $\mathrm{H}_{2} \mathrm{O}$. The organic layer dried over $\mathrm{MgSO}_{4}$, filtrated and concentrated in vacuo. Purification by column chromatography pentane/EtOAc 9:1 to 1:1 pentane/EtOAc yielded the crude ( 63.2 g ) with benzyl alcohol traces. The crude was dissolved in a mixture of $4 \mathrm{M} \mathrm{HCl}(\mathrm{aq})$ /dioxane ( $800 \mathrm{ml}, 0.15 \mathrm{M} \mathrm{v} / \mathrm{v}=1: 1$ ) and the mixture was heated at $80^{\circ} \mathrm{C}$ for 2.5 h and was then left stirring overnight at rt . The mixture was reheated at $80^{\circ} \mathrm{C}$ for 1.5 h and was then poured into 200 ml sat aq. $\mathrm{NaHCO}_{3}$ after cooling down. $\mathrm{Na}_{2} \mathrm{CO}_{3}$ was added to neutralize the mixture and the mixture was diluted with EtOAc. The organic layer was washed with
water and brine, dried over $\mathrm{MgSO}_{4}$, filtrated and concentrated in vacuo. Purification by column chromatography pentane/EtOAc 8:2 to 4:6 pentane/EtOAc yielded a mixture of product and starting material. The mixture was dissolved in $\mathrm{MeOH}(375 \mathrm{ml} ; 0.20 \mathrm{M}$ ) and $\mathrm{NaBH}_{4}$ ( $3.7 \mathrm{~g} ; 98.0 ; 1.3$ eq.) was added at $0^{\circ} \mathrm{C}$ in 2 portions and the mixture was stirred 4 days at rt . Then the reaction was quenched with EtOAc, concentrated under reduced pressure and co-evaporated with toluene. Purification by column chromatography pentane/EtOAc 1:0 to 2:8 pentane/EtOAc yielded the product 11 in $50 \%$ over 3 steps (21.7 g; 58.3 mmol$).[\alpha]_{\mathrm{D}}{ }^{20}\left(\mathrm{CHCl}_{3} \mathrm{C} 1\right)$ :+ 19.4; IR (neat, $\mathrm{cm}^{-1}$ ): 3383, 2924, 2872, 1717, 1506, 1456, 1096, 1070, 1028, 737, 698; ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta=2.86$ (bs, 1H, OH), 3.22 (bs, 1H, OH), 3.49-3.56 (m, 2H, H-C-OH, CHH), 3.74-3.87 (m, 4H, CH $-\mathrm{OH}, 2 \mathrm{CH}-\mathrm{Rbo}$ ), 3.91-4.00 (m, 3H, CHH, CH-CH2), 4.58-4.66 (m, 3H, CH2-Bn), $4.73(\mathrm{~d}, 1 \mathrm{H}, \mathrm{J}=11.2 \mathrm{~Hz}$, CHH-Bn), 5.14-5.27 (m, 2H, CH=CH $)_{2}$, 5.82-5.92 (m, 1H, CH=CH2), 7.24-7.35 (m, 10H, H-arom); ${ }^{13} \mathrm{C}$-APT NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta=60.9\left(\mathrm{CH}_{2}-\mathrm{OH}\right), 70.5(\mathrm{CH}-\mathrm{OH}), 71.171 .9,72.2$, $73.9\left(\mathrm{CH}_{2}-\mathrm{Rbo} / \mathrm{CH}_{2}-\mathrm{CH}, 2 \times \mathrm{CH}_{2}-\mathrm{Bn}\right), 79.4$ ( $2 \mathrm{xH} \mathrm{CH}-\mathrm{Rbo}$ ), $117.4\left(\mathrm{CH}=\mathrm{CH}_{2}\right), 127.8,127.9,128.0$, 128.4, 128.4 (C-arom), 134.5 ( $\mathrm{CH}=\mathrm{CH}_{2}$ ), 138.1, 138.1 (Cq-arom); HRMS: [M+Na] ${ }^{+}$calculated for $\mathrm{C}_{22} \mathrm{H}_{28} \mathrm{O}_{5} \mathrm{Na} 395.1834$, found 395.1831 .
