In brief

Using genetic, chimeric, and pharmacologic approaches, Pack et al. demonstrate that the parasite-derived crystal hemozoin erodes conventional CD8 α^+ type 1 dendritic cell (cDC1) abundance and function in an NLRP3 inflammasome-dependent manner, which results in reduced CD4⁺ T follicular helper cell differentiation and impaired anti-*Plasmodium* humoral immunity.

Highlights

- Hemozoin engages NLRP3 to reduce CD8 α^+ dendritic cell (DC) number and function
- Impaired DC responses compromise the B cell helper functions of CD4⁺ T cells
- The accumulation of hemozoin reduces memory B cell and plasma cell responses
- NLRP3 deficiency boosts humoral immune memory-mediated protection

SUMMARY

During acute malaria, most individuals mount robust inflammatory responses that limit parasite burden. However, long-lived sterilizing anti-malarial memory responses are not efficiently induced, even following repeated *Plasmodium* exposures. Using multiple *Plasmodium* species, genetically modified parasites, and combinations of host genetic and pharmacologic approaches, we find that the deposition of the malarial pigment hemozoin directly limits the abundance and capacity of conventional type 1 dendritic cells to prime helper T cell responses. Hemozoin-induced dendritic cell dysfunction results in aberrant *Plasmodium*-specific CD4 T follicular helper cell differentiation, which constrains memory B cell and long-lived plasma cell formation. Mechanistically, we identify that dendritic cell-intrinsic NLRP3 inflammasome activation reduces conventional type 1 dendritic cell abundance, phagocytosis, and T cell priming functions *in vivo*. These data identify biological consequences of hemozoin deposition during malaria and highlight the capacity of the malarial pigment to program immune evasion during the earliest events following an initial *Plasmodium* exposure.

INTRODUCTION

Nearly half of the world's population lives in areas endemic to the disease syndrome malaria, which is caused by infection with protozoan parasites of the genus *Plasmodium*. Children under the age of 5 account for two-thirds of all malaria-associated mortality (WHO, 2019). Repeated parasite infections generally fail to elicit sterilizing immunity, even following years of exposure among those living in regions of intense *Plasmodium* transmission (Tran et al., 2013). The emergence of parasite resistance to front-line antimalarial drugs (Das et al., 2018), coupled with the limited capacity of existing vaccines to elicit protection in endemic populations (Mensah et al., 2016; Rts, 2015), underscores the rationale for continued efforts to close knowledge gaps regarding the mechanisms, whether host or parasite associated, that restrict the development of durable, protective immune memory responses.

Following an initial *Plasmodium* infection and asymptomatic replication of parasites in the liver, schizont-induced rupture of parasite-infected red blood cells (pRBCs) liberates both host- and parasite-derived factors, including host RBC membranes,

parasite antigens, and nucleic acids, that are recognized and often captured by host phagocytes. These stimuli rapidly induce the activation of macrophages and dendritic cells (DCs) that produce reactive oxygen and nitrogen species (Chua et al., 2013; Ranjan et al., 2016; Sobolewski et al., 2005; Sponaas et al., 2009), which are believed to limit infection intensity prior to the induction and orchestration of anti-*Plasmodium* cellular and humoral immunity. Phagocytes are also responsible, in part, for the production of high levels of proinflammatory cytokines such as interleukin (IL)-1 β , IL-12, and interferon (IFN)- γ that both amplify the activation and recruitment of additional effector immune cells (Leisewitz et al., 2004; Perry et al., 2005; Wykes et al., 2007) and contribute to clinical malarial disease syndrome (deWalick et al., 2007). In addition to initiating and amplifying host immunity, DCs also contribute to the initiation of T follicular helper (T_{FH}) cell differentiation via MHC II-restricted antigen presentation and costimulation (Choi et al., 2011; Langenkamp et al., 2000). T_{FH} populations, in turn, are critical for orchestrating protective pathogen-specific humoral responses and deficiencies in anti-malarial humoral immunity have been linked to altered T_{FH} development and function (Hansen et al., 2017; Ryg-Cornejo

et al., 2016; Zander et al., 2016; Zander et al., 2015). Whether DCs are distinctly programmed during *Plasmodium* blood-stage infection such that they inefficiently support the development of anti-*Plasmodium* T_{FH} responses and humoral immunity is not well defined.

During either *in vivo* blood-stage infection or following direct *in vitro* incubation with pRBCs, DCs exhibit an atypical maturation phenotype (Elliott et al., 2007; Götz et al., 2017; Urban et al., 1999), as well as reduced responsiveness to LPS stimulation and impaired capacity to initiate heterologous immune responses during an active *Plasmodium* infection (Lundie et al., 2010; Millington et al., 2006). Compared to DCs from uninfected subjects, myeloid DCs isolated from the peripheral blood of *P. falciparum* exposed individuals expressed lower levels of CD80, CD86, and HLA-DR following *in vitro* stimulation with blood-stage parasites (Turner et al., 2021). *In vitro* incubation of DCs with intact and dissociated pRBCs, along with RBC ghosts (membranes), identified that hemozoin, a crystalized parasite-derived hemoglobin degradation byproduct and NLRP3 inflammasome and CLEC12A agonist (Kalantari et al., 2014; Raulf et al., 2019; Shio et al., 2009), can alter DC function (Schwarzer et al., 1998; Skorokhod et al., 2004). However, whether modulating hemozoin levels in the context of natural *Plasmodium* blood-stage infection directly impacts DC-dependent development of anti-*Plasmodium* humoral responses has not been investigated.

In this report, we combined genetic, chimeric, and pharmacologic approaches to interrogate whether hemozoin exposure during experimental malaria impacts immune programming and the development of protective anti-*Plasmodium* humoral immune memory responses. Using both genetically modified *Plasmodium berghei* (*Pb*) parasites engineered to produce 10-fold lower levels of hemozoin (Lin et al., 2015) and wild-type *P. yoelii* infection of NLRP3-deficient mice, we show that hemozoin-induced, DC-intrinsic NLRP3-mediated inflammasome activation compromises T_{FH} differentiation, which in turn limits anti-*Plasmodium* memory B cell and the long-lived plasma cell responses and protective humoral immunity against malaria.

RESULTS

Durable anti-*Plasmodium* humoral immunity is compromised by hemozoin

To address whether hemozoin formation and deposition influences the generation of durable anti-malarial immunity, we established memory immune responses in wild-type C57BL/6 mice by infecting them with a genetically modified *Plasmodium berghei* ANKA variant lacking the aspartic proteases plasmepsin 4 and berghepain-2 ($\Delta pm4\Delta bp2$), genes that are necessary for efficient degradation of hemoglobin and crystallization of hemozoin (Lin et al., 2015; Spaccapelo et al., 2010). Mature schizonts of $\Delta pm4\Delta bp2$ parasites produce less hemozoin compared to wild-

type (WT) *P. berghei* ANKA parasites with 50% reductions in hemozoin accumulation within the spleen as early as day 5 post-infection (p.i.) (Figure S1A). Because $\Delta pm4\Delta bp2$ parasites also exhibit reduced growth and replication *in vivo* compared to WT *Pb* ANKA parasites (Lin et al., 2015), other groups of mice were infected with a comparison mutant of growth-attenuated *P. berghei* lacking leucyl aminopeptidase (Δlap), a mutant that is not impaired in hemozoin production (Lin et al., 2015) but exhibits growth and clearance kinetics that are equivalent to $\Delta pm4\Delta bp2$ parasites (Figure S1B). These genetically modified parasites enabled us to directly address the *in vivo* role of hemozoin and avoid major caveats associated with injection of exogenous hemozoin, including the form (i.e., synthetic or natural), site of accumulation, and dose (Pham et al., 2021). Sixty days after the initial infection with either Δlap or $\Delta pm4\Delta bp2$ parasites, we challenged both groups of mice with WT (virulent) *P. berghei* ANKA parasites engineered to express the fusion protein GFP-Luciferase (*Pb*-ANKA-Luc) (Figure 1A). Compared to Δlap -immune mice, $\Delta pm4\Delta bp2$ -immune mice exposed to lower levels of hemozoin during primary infection exhibited reduced parasitemia (Figure 1B) and total parasite biomass luminescence (Figure 1C) across all time points examined and whole-body bioluminescent imaging revealed substantial *Pb*-ANKA-Luc tissue accumulation in Δlap -immune mice that was absent in $\Delta pm4\Delta bp2$ -immune mice (Figure 1C). $\Delta pm4\Delta bp2$ -immune mice also exhibited 100% survival following WT *Pb*-ANKA-Luc challenge (Figure 1D).

Because $\Delta pm4\Delta bp2$ -immune mice exhibited enhanced control of WT *Pb*-ANKA as early as days 3–4 post-challenge, relative to Δlap -immune mice (Figure 1B), we further posited that the observed resistance to virulent *Pb*-ANKA-Luc challenge could be attributed to pre-existing, protective anti-*Plasmodium* antibodies. Consistent with this hypothesis, passive transfer of purified immunoglobulin G (IgG) from $\Delta pm4\Delta bp2$ -immune donors to WT *Pb*-ANKA-infected recipient mice (Figure 1E) transiently resulted in a 75% reduction in parasitemia, compared to transfer of an equivalent amount of purified IgG from Δlap -immune donors (Figure 1F), although immune IgG transfer was not sufficient to protect recipients beyond the first week (Figure S1C). Strikingly, antibody titers directed against the 19 kDa fragment of Merozoite Surface Protein 1 (MSP1₁₉), an immunodominant and protective blood-stage antigen (John et al., 2004; O'Donnell et al., 2001; Terrientes et al., 1994), were not detectably different between Δlap and $\Delta pm4\Delta bp2$ -immune mice (Figure S1D), and we found no significant alterations in the total IgG antibody avidity index or isotype class distributions (Figures S1E and S1F). Nevertheless, our passive transfer data are consistent with an enhanced long-lived antibody response in $\Delta pm4\Delta bp2$ -immune mice, compared to Δlap -immune mice, which may be reflected by either quantitative or qualitative (specificity and functional) shifts that register below the sensitivity of these assays.

Secreted anti-*Plasmodium* antibodies that are present 60 days p.i. likely derive from long-lived plasma cells (LLPCs) that often

reside in the bone marrow (Lightman et al., 2019). Given the enhanced protective capacity of $\Delta pm4\Delta bp2$ -immune IgG, we quantified parasite-specific LLPC in the bone marrow during the memory phase. By day 40 p.i., we found approximately 2-fold greater numbers of CD138^{hi}TACI^{hi}CD19^{lo}B220^{lo} mature resting LLPC (Pracht et al., 2017) (Figures 1G and 1H) and functional MSP1₁₉-specific IgG secreting cells (Figure 1I; Figure S1G) in the bone marrow of $\Delta pm4\Delta bp2$ -immune mice, compared to Δlap -immune mice. Thus, we next evaluated the kinetics of parasite-specific LLPC formation. As early as day 14 p.i., the frequency and number of splenic CD38⁺IgD^{neg}CD138^{hi} LLPC precursors expressing CXCR4, a chemokine receptor associated with bone marrow homing (Nie et al., 2004), was 30%–40% greater in $\Delta pm4\Delta bp2$ -infected mice (Figures 1J and 1K). By day 28 p.i., the bone marrow of $\Delta pm4\Delta bp2$ -immune mice presented with twice as many CD38⁺IgD^{neg}CD138^{hi}TACI^{hi} LLPC (Figure 1L) and MSP1₁₉-specific IgG-secreting cells (Figure 1M), compared to Δlap -immune mice. Taken together, these data support that deposition of hemozoin during a primary blood-stage *Plasmodium* exposure impairs either the development or function of LLPC and durable anti-*Plasmodium* humoral responses.

Hemozoin compromises memory B cell responses

Given the deleterious effect of hemozoin on LLPC development and function following primary blood-stage infection, we addition-

ally hypothesized that hemozoin may interfere with the development and function of memory B cell (MBC) populations. Consistent with this hypothesis, splenic CD19⁺CD38⁺IgD^{neg}CD73⁺CD95^{neg} MBC and CD19⁺CD38⁺IgD^{neg}CD73⁺CD80⁺PD-L2⁺ MBC, with CD80⁺PD-L2⁺ defining those most capable of rapid antibody production (Zuccarino-Catania et al., 2014), were elevated 2-fold by day 30 p.i. in $\Delta pm4\Delta bp2$ -immune mice, compared to Δlap -immune mice (Figures 2A–2D). The chemokine receptor CCR6 is reported to enhance cell positioning within secondary lymphoid tissues for superior recall upon pathogen challenge (Elgueta et al., 2015; Suan et al., 2017) and by day 60 p.i., the frequency of splenic MBC cells expressing CCR6 were 2- to 3-fold greater in $\Delta pm4\Delta bp2$ -immune mice, compared to Δlap -immune mice (Figures 2E–2G). To interrogate functional MBC responses, we evaluated MSP1₁₉-specific serum antibody titers in $\Delta pm4\Delta bp2$ and Δlap -immune mice both prior to and 5 days after challenge with WT *Pb*-ANKA. In this short interval, increases in MSP1₁₉-specific, isotype-switched IgG titers are most likely due to MBC activation and differentiation into plasma cells, rather than *de novo* humoral immune responses. Although $\Delta pm4\Delta bp2$ -immune mice harbor 2-fold higher numbers of MBC (Figures 2A–2D), 5 days after challenge MSP1₁₉-specific IgG titers expanded by 10-fold, as compared to 3-fold in Δlap -immune mice (Figure 2H). Together, these data suggest that recall functions of MBC are impaired by the presence and deposition of hemozoin.

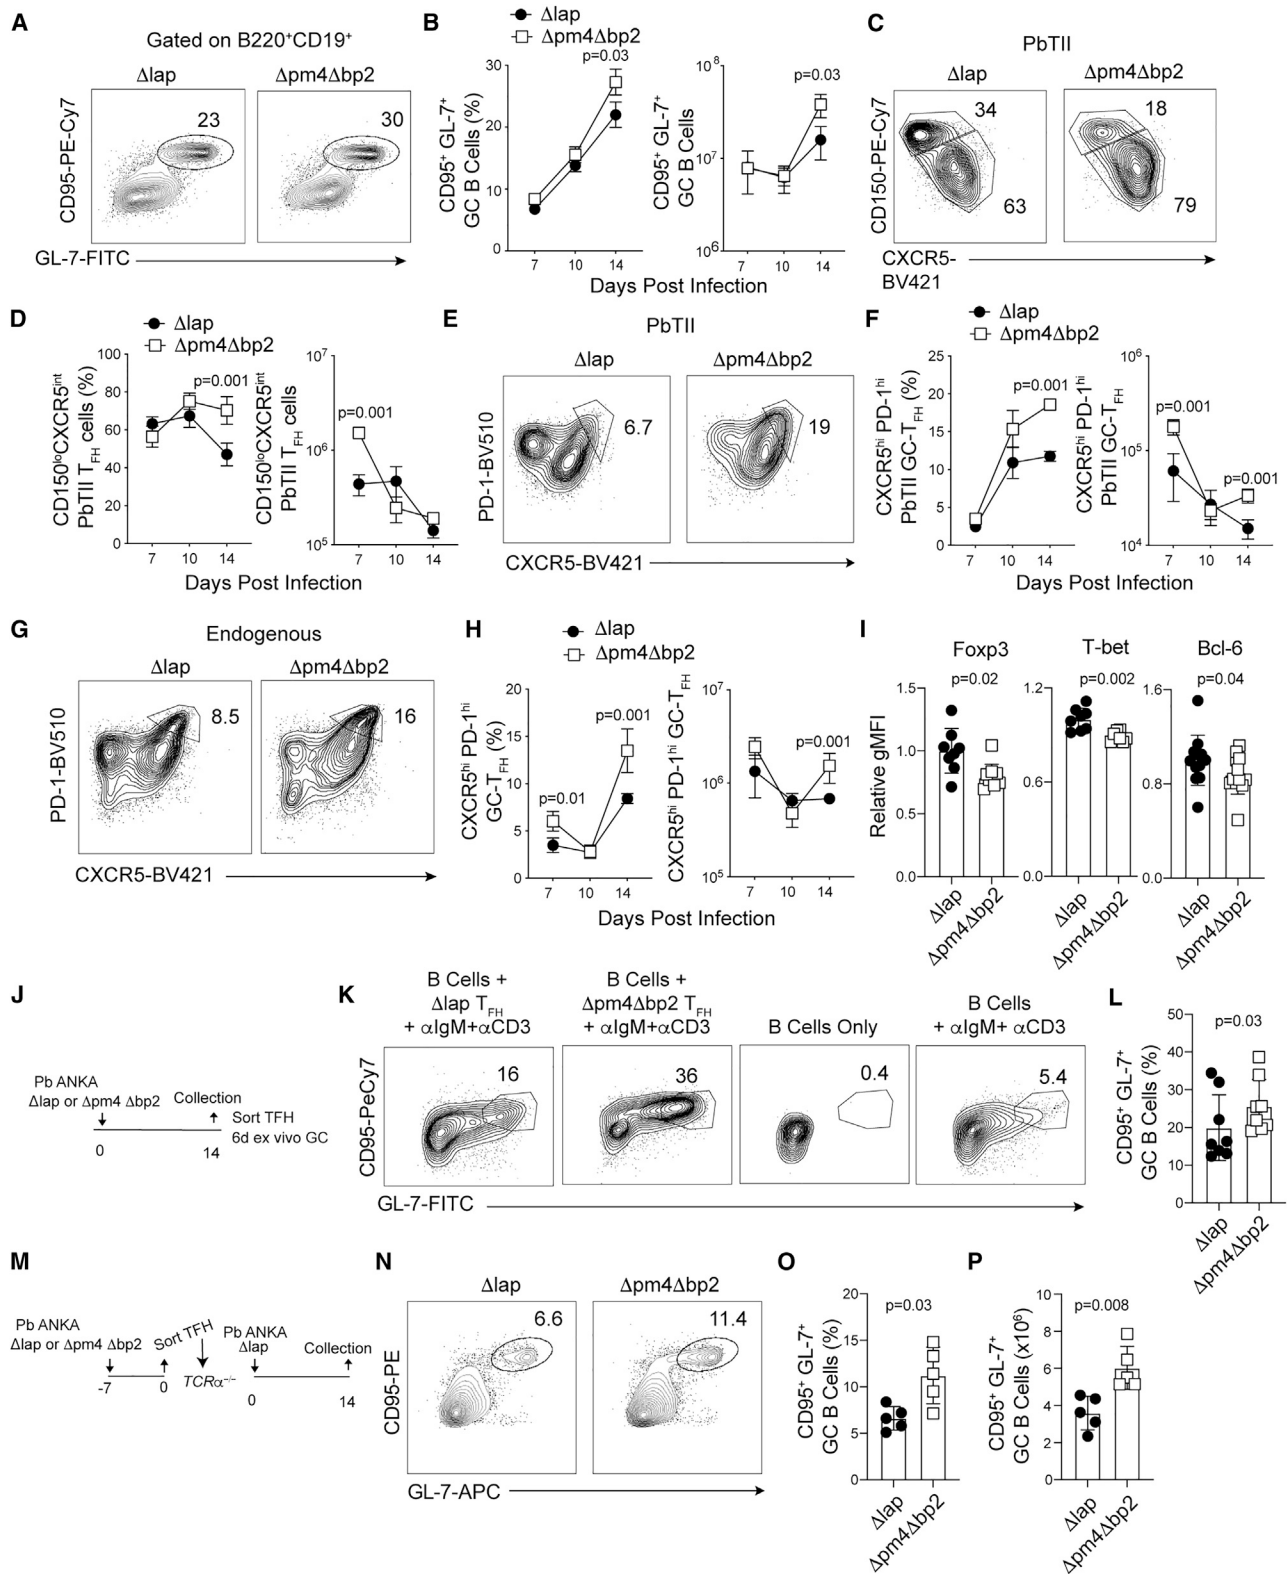

Figure 3. Hemozoin impairs the germinal center response

Parasite-specific CD4 T cells (PbTII) were transferred to C57BL/6 mice 1 day prior to infection with either $\Delta pm4\Delta bp2$ or Δlap parasites. Splenic T_{FH} and GC B cell responses were evaluated.

(legend continued on next page)

CD4 T cell help and germinal center B cell responses are impaired by hemozoin

LLPC and MBC populations derive from germinal center (GC) B cell responses (Mesin et al., 2016; Weisel et al., 2016) and hemozoin deposition was associated with reduced LLPC and MBC development as early as days 14 and 30 p.i. in $\Delta pm4\Delta bp2$ -infected mice, time points that encompass the peak of GC B cell responses following experimental *Plasmodium* (Krishnamurthy et al., 2016; Vijay et al., 2020). Indeed, by day 14 p.i. the frequency and number of CD95⁺GL-7⁺ GC B cells were elevated by ~30% in $\Delta pm4\Delta bp2$ -infected mice, compared to Δlap -infected mice (Figures 3A and 3B). Because GC B cell responses depend on the presence and activity of T_{FH} cells (Kräutler et al., 2017), we next postulated that hemozoin impairs either the induction, stepwise differentiation, or function of T_{FH} populations. To test this hypothesis, we transferred *Plasmodium*-specific CD4 T cell receptor transgenic cells (PbTII [Fernandez-Ruiz et al., 2017]) to WT mice, infected recipients 1 day later with either $\Delta pm4\Delta bp2$ or Δlap parasites and then quantified both polyclonal, endogenous and PbTII CD4 T cells exhibiting characteristics of either mature CXCR5^{hi}PD-1^{hi} GC-T_{FH} cells that localize to follicular GC reactions or their extrafollicular CD150^{lo}CXCR5^{int} T_{FH} precursors (Choi et al., 2011; Crotty, 2014). By day 14 p.i., we found 30%–50% increases in the frequencies and numbers of both CD150^{lo}CXCR5^{int} T_{FH} precursors (Figures 3C and 3D) and mature CXCR5^{hi}PD-1^{hi} GC-T_{FH} subsets (Figures 3E and 3F) among PbTII cells in $\Delta pm4\Delta bp2$ -infected mice, compared to PbTII cells in Δlap -infected mice. We also observed 2-fold greater numbers of CXCR5^{hi}PD-1^{hi} GC-T_{FH} cells among polyclonal endogenous CD4 T cells recovered from $\Delta pm4\Delta bp2$ -infected mice (Figures 3G and 3H), supporting the view that this effect extends to the endogenous CD4 T cell receptor repertoire. Bcl-6 is a transcriptional repressor that is essential for T_{FH} differentiation and function (Hatzi et al., 2015) and T-bet⁺ T_{H1}-like T_{FH} and Foxp3⁺ T regulatory cells are reported to constrain anti-*Plasmodium* humoral immunity (Kurup et al., 2017; Obeng-Adjei et al., 2015). However, on 14 p.i., we identified only modestly reduced levels of T-bet and Foxp3, and equivalent expression levels of Bcl-6, in mature GC-T_{FH} cells recovered from $\Delta pm4\Delta bp2$ -infected mice, compared to mature GC-T_{FH} cells recovered from Δlap -infected animals (Figure 3I; Figure S2A). Despite these modest cell-intrinsic transcriptional differences, we additionally tested whether mature GC-T_{FH} cells recovered from $\Delta pm4\Delta bp2$ -infected mice differed in their capacity to promote GC B cell differentiation. We sort-purified mature CXCR5^{hi}PD-1^{hi} GC-T_{FH} from each group and co-cultured cells with an equivalent number with naive B cells for 5 days (Fig-

ure 3J). We observed significant increases in the proportions of B cells exhibiting a CD95⁺GL-7⁺ GC phenotype when cells were cultured with mature GC-T_{FH} recovered from $\Delta pm4\Delta bp2$ -infected mice, compared to mature GC-T_{FH} cells recovered from Δlap -infected mice (Figures 3K and 3L). Moreover, T_{FH} cells sort-purified on day 7 p.i. from the spleens of Δlap -infected mice were also impaired in their capacity to drive GC responses following transfer to *Tcrα*^{-/-} recipients, compared to T_{FH} recovered from $\Delta pm4\Delta bp2$ -infected mice (Figures 3M–3P; Figures S2B–S2D). Together, these data support that the presence of elevated levels of hemozoin impairs the differentiation and cell-intrinsic function of T_{FH} cells with subsequent reductions in GC B cell responses.

Conventional DC functions are compromised by hemozoin

CD11c⁺B220^{neg} conventional dendritic cells (cDCs), particularly the CD11b^{neg}CD8α⁺ conventional type 1 DC (cDC1) subset, are critical for initiating protective T cell responses against blood-stage *Plasmodium* infection (Fernandez-Ruiz et al., 2017; Voisine et al., 2010). Total CD11c⁺B220^{neg} cDC numbers, phagocytic functions, and cytokine expression are reported to progressively decline during the course of experimental and clinical malaria, which has been described as immunoparalysis (Loughland et al., 2016; Lundie et al., 2010; Pinzon-Charry et al., 2013; Woodberry et al., 2012). Moreover, purified hemozoin can down-modulate DC reactivity following direct co-incubation *ex vivo* (Millington et al., 2006; Skorokhod et al., 2004). However, whether the deposition and/or accumulation of hemozoin specifically impairs either total cDC or cDC1 functions during blood-stage *Plasmodium* infection *in vivo* has not been directly tested. To investigate this, we examined cDC subset abundance, costimulatory receptor expression, and phagocytic function in $\Delta pm4\Delta bp2$ and Δlap -infected mice (representative gating, Figure S3A). As early as day 4 p.i., we found elevated numbers of CD11c⁺B220^{neg} cDCs in $\Delta pm4\Delta bp2$ -infected mice, compared to their Δlap -infected counterparts (Figures 4A and 4B). These increases were primarily associated with elevated frequencies and numbers of CD11b^{neg}CD8α⁺ cDC1 in $\Delta pm4\Delta bp2$ -infected mice (Figures 4C–4E) expressing elevated levels of MHC II (Figures 4F and 4G). Although expression of the costimulatory molecule CD80 was unaffected by hemozoin abundance (Figures 4H and 4I), CD86 expression was significantly increased on CD11b^{neg}CD8α⁺ cDC1 recovered from $\Delta pm4\Delta bp2$ -infected mice (Figures 4J and 4K). Relative to cells from Δlap -infected mice, similar frequencies of cDC1 from $\Delta pm4\Delta bp2$ -infected mice exhibited the capacity to phagocytose fluorescent carboxylate beads and OVA protein, but the quantities of each

phagocytosed reagent (gMFI) were significantly elevated (Figures 4L–4O). Enhanced cDC1 function was also observed in antigen processing, as CD11b^{neg}CD8 α ⁺ cDC1 DCs recovered from $\Delta pm4\Delta bp2$ -infected mice exhibited more efficient ovalbumin (OVA) protein cleavage and endosomal accumulation, compared to cDC1 recovered from Δlap -infected mice (Figures 4P and 4Q). Compromises in cDC antigen accumulation and processing and MHC II and costimulatory receptor expression were further magnified by the second week of primary infection in Δlap -infected mice (Figures S3B–S3I). Of note, CD11b⁺CD8 α ^{neg} cDC2 functions were also impacted by the abundance of hemozoin, although these impacts were more modest (Figures S3J–S3L). Finally, and despite the caveats associated with dose, schedule, and formulation, we also found that direct injection of synthetic hemozoin into $\Delta pm4\Delta bp2$ -infected mice reversed the enhanced cDC1 abundance (Figures S4A–S4C), MHC II expression (Figures S4D and S4E), and antigen processing (Figures S4F and S4G). These data phenocopy parameters observed in Δlap -infected mice and serve as an additional complementary approach to show that hemozoin impairs cDC1 functions during *Plasmodium* infection.

Hemozoin limits early CD4 T cell expansion and differentiation

Given the changes we observed in cDC number, phenotype, and function, we further tested whether hemozoin impaired the capacity of cDC to prime *Plasmodium*-specific CD4 T cells. PbTII activation and division, as evidenced by CTV dilution, was first evaluated on day 4 p.i., which corresponds to a time point matching our kinetic analyses of impaired cDC function (Figure 4) and the reported development of cDC immunoparalysis (Lundie et al., 2010). Consistent with our cDC phenotypic and functional analyses, reduced levels of hemozoin in $\Delta pm4\Delta bp2$ -infected mice increased the capacity of antigen-presenting cells (APCs) to support parasite-specific T cell proliferation (Figure 5A). There were nearly 20% increases in the proportion of PbTII that proliferated and nearly 50% increases in the proportion of divided PbTII cells that differentiated into CD150^{lo}CXCR5^{int} T_{FH} precursor cells (Figures 5B and 5C). APC:CD4 T cell interactions are also crucial for helper cell migration into the GC, and this transition is regulated in part by either the strength of TCR stimulation (Benson et al., 2015; Goenka et al., 2011; Moran et al., 2011; Zemmour et al., 2018) or dwell time with APC (González et al., 2005; Govern et al., 2010). To investigate these aspects of cDC function, we transferred Nur77-GFP PbTII reporter cells to both $\Delta pm4\Delta bp2$ and Δlap -infected mice and found that reduced levels of hemozoin in $\Delta pm4\Delta bp2$ -infected mice significantly enhanced TCR stimulation strength (Figures 5D and 5E), which likely contributes to the expanded number and proportion of T_{FH} cells in $\Delta pm4\Delta bp2$ -infected mice (Figure 3 and Figures 5B and 5C). In contrast to day 14 p.i. CXCR5^{hi}PD-1^{hi} mature GC-T_{FH} (Figure 3I), we found elevated Bcl-6 expression among CD150^{lo}CXCR5^{int} T_{FH} precursor cells on days 7 and 10 p.i. (Figure 5F) in mice exposed to reduced levels of hemozoin. Importantly, the skewing of CD4 T cells toward a GC T_{FH} fate in $\Delta pm4\Delta bp2$ -infected mice was cDC intrinsic, as *ex vivo* co-culture of GP_{66–77} peptide-pulsed cDCs isolated from $\Delta pm4\Delta bp2$ -infected mice resulted in both enhanced proliferation (Figures 5G and 5H) and trending upregulation of PD-1 and CXCR5 by GP_{66–77}-specific TCR trans-

genic SMARTA CD4 T cells (Figures 5I and 5J). Notably, and similar to the cDC datasets, injection of synthetic hemozoin into $\Delta pm4\Delta bp2$ -infected mice reversed the enhanced parasite-specific T_{FH} differentiation phenotypes (Figures S4H and S4I). Taken together, these data support that cDC are numerically and functionally compromised by hemozoin and this alters their capacity to optimally induce CD4 T cell responses and T_{FH} differentiation during blood-stage *Plasmodium* infection.

NLRP3 activation prevents the development of optimal T_{FH} and humoral responses

To interrogate the mechanisms by which hemozoin erodes cDC numbers and function, with subsequent impacts in T_{FH} cell development and humoral immunity, we focused on the NLRP3 inflammasome. *In vitro* data support that hemozoin engages and activates the NLRP3 inflammasome (Kalantari et al., 2014; Shio et al., 2009; Strangward et al., 2018), and we found that serum IL-1 β levels were on average 75% lower in mice infected with $\Delta pm4\Delta bp2$ parasites, compared to mice infected with Δlap parasites (Figure S5A). Thus, we next tested whether the enhanced T_{FH} cell differentiation phenotypes we observe in $\Delta pm4\Delta bp2$ -infected mice were formally linked to NLRP3 inflammasome activation. To do this, we first transferred WT PbTII CD4 T cells to both C57BL/6 (WT) and NLRP3 deficient (KO) mice and subsequently infected the recipients with either Δlap or $\Delta pm4\Delta bp2$ parasites. Consistent with our previous observations (Figure 3), we found reduced frequencies of both PbTII CD150^{lo}CXCR5^{int} T_{FH} precursors and CXCR5^{hi}PD-1^{hi} mature GC-T_{FH} populations in Δlap -infected WT mice, compared to $\Delta pm4\Delta bp2$ -infected WT mice (Figure 6A, left panels). Strikingly, PbTII T_{FH} and GC-T_{FH} development in both Δlap -infected NLRP3 KO mice and WT mice treated from days 0 to 6 p.i. with the NLRP3 inflammasome inhibitor MCC950 phenocopied PbTII T_{FH} differentiation in $\Delta pm4\Delta bp2$ -infected WT mice (Figure 6A, right panels). NLRP3 activation also impaired the capacity of GC-T_{FH} to promote GC B cell responses, as mature GC-T_{FH} cells sort-purified from Δlap -infected NLRP3 KO mice induced 2-fold greater numbers of GC B cell in *ex vivo* co-culture assays, compared to GC-T_{FH} cells recovered from Δlap -infected WT mice (Figure 6B). In addition to the deleterious impact of NLRP3 activation on T_{FH} differentiation and function, the frequency and number of splenic GC B cells (Figures S5B and S5C) and CD95^{neg}CD73⁺CD80⁺PD-L2⁺ MBC (Figures 6C and 6D) were significantly decreased by either the presence of hemozoin or NLRP3 inflammasome activity.

To directly address whether hemozoin-mediated NLRP3 activation compromises long-term protective immunity *in vivo*, groups of both WT and NLRP3 KO mice were immunized with either $\Delta pm4\Delta bp2$ or Δlap parasites and then challenged with WT *Pb*-ANKA after 60 days (Figure 6E). Both WT and NLRP3 KO mice immunized with $\Delta pm4\Delta bp2$ exhibited 100% survival and reduced parasite burden (Figures 6F, S5D, and S5E) through day 35 p.i. However, more than 75% of Δlap -immune NLRP3 KO mice survived, compared to only 30% of Δlap -immune WT mice (Figure 6F). We also found functional MBC recall antibody responses were substantially improved in $\Delta pm4\Delta bp2$ -immune WT mice and Δlap -immune NLRP3 KO mice, as evidenced by 38- and 169-fold boosts in parasite-specific IgG titers 5 days

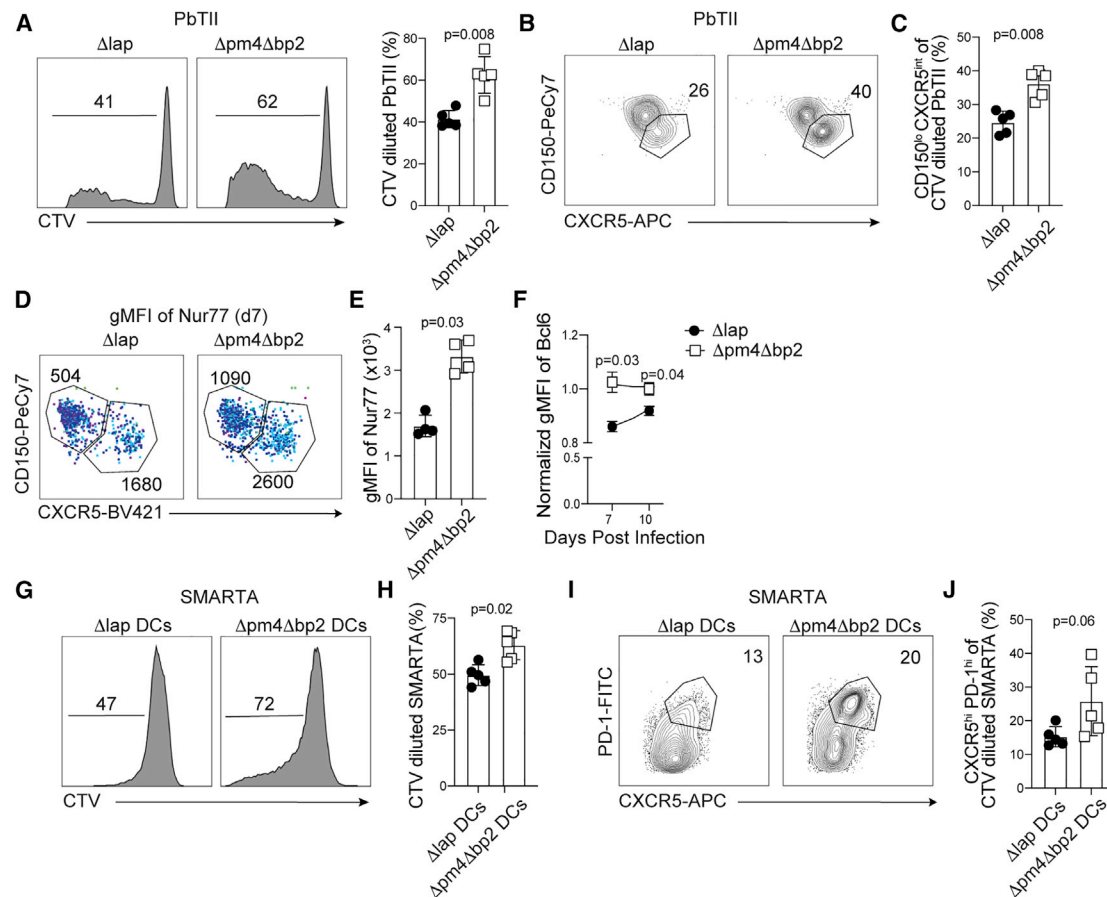

Figure 5. Optimal T_{FH} expansion is impaired by hemozoin

CTV-labeled PbTII cells were transferred into mice 1 day prior to infection with either $\Delta pm4\Delta bp2$ or Δlap -infected parasites and harvested 4 days later.

after *Pb*-ANKA challenge, respectively (Figure 6G), in contrast to the modest 7-fold boost in Δlap -immune WT mice. Collectively, these experiments show that the infection of NLRP3-deficient mice with Δlap parasites effectively phenocopies elevated GC-T_{FH} and MBC numbers and functions observed following infection of WT mice with $\Delta pm4\Delta bp2$ parasites, further supporting that hemozoin-mediated NLRP3 activation impairs protective anti-*Plasmodium* humoral immunity.

Cell-intrinsic NLRP3 activation impairs cDC number and function

Our genetic and pharmacological approaches support that hemozoin-mediated NLRP3 inflammasome activation constrains T_{FH} dependent humoral immunity. To determine whether these

phenotypes are mechanistically linked to cDC-intrinsic NLRP3 activity and confirm that our findings extend beyond study of the mutant *Pb* ANKA parasites, we first evaluated cDC numbers and functions and T_{FH} development in WT and NLRP3 deficient mice infected with *Plasmodium yoelii* parasites (Figure 7A). We observed that the total numbers of CD11b^{neg}CD8 α ⁺ cDC1 (Figures 7B and 7C), and their relative MHC II expression (Figure 7D) were significantly increased in the absence of NLRP3 activation. Moreover, the capacity of cDC1 from *P. yoelii*-infected mice to both phagocytose multiple carboxylate beads (gMFI) (Figure 7E) and functionally process and accumulate cleaved OVA protein (Figures 7F and 7G) was markedly enhanced in the absence of hemozoin-mediated NLRP3 inflammasome activation, which closely resembles our findings with the mutant *Pb* ANKA

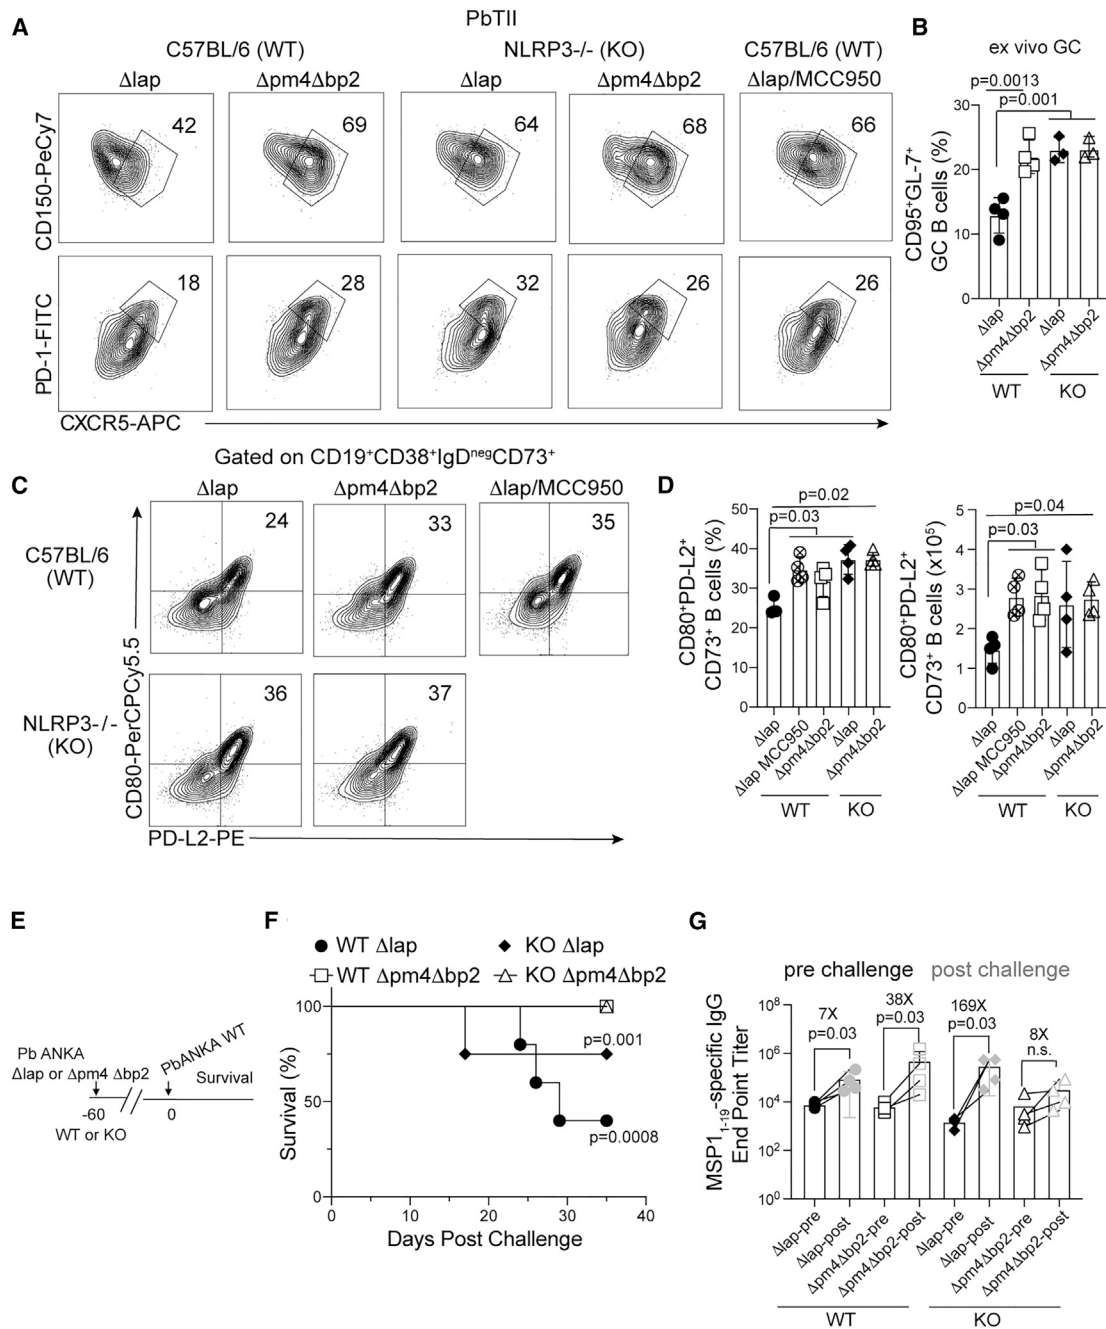

Figure 6. Hemozoin-mediated impairments in humoral immunity are governed by NLRP3

PbTII cells were transferred to C57BL/6 and NLRP3^{-/-} mice 1 day prior to infection with either $\Delta pm4\Delta bp2$ or Δlap parasites. Splenic GC responses were evaluated on day 14 p.i.

(A) Representative flow plots of CD150^{lo}CXCR5^{int} T_{FH} and CXCR5^{hi}PD-1^{hi} GC-T_{FH} populations.

(B) CXCR5^{hi}PD-1^{hi} GC-T_{FH} cells were sort purified on day 14 p.i., co-cultured with naive B cells, and the frequency of CD95⁺GL-7⁺ GC B cells was quantified after 5 days.

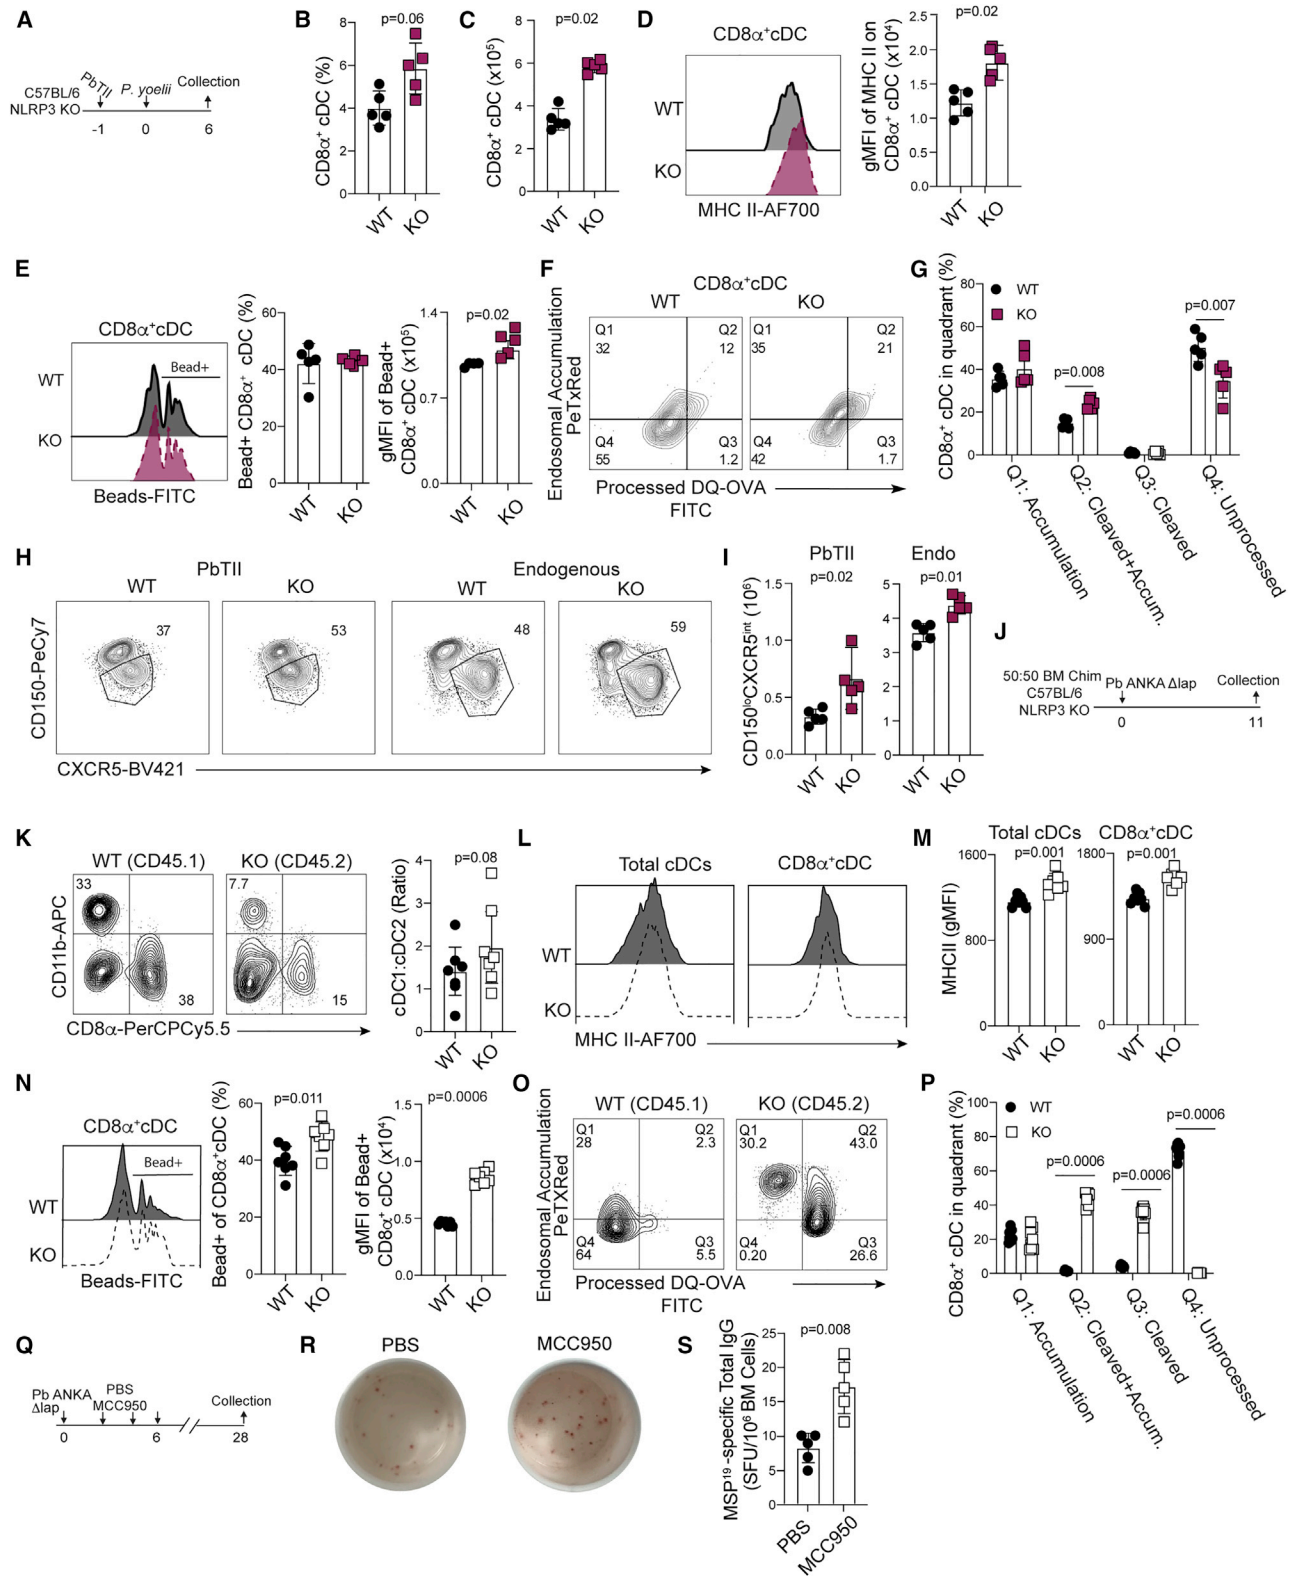

(C and D) Representative flow plots (C) and frequency (D) of CD80⁺PD-L2⁺CD73⁺CD38⁺CD95^{neg} MBC on day 28 p.i.

(E) C57BL/6 and NLRP3^{-/-} mice were immunized with $\Delta pm4\Delta bp2$ and Δlap parasites 60 days prior to challenge with a virulent Pb-ANKA strain.

(F) Frequency of immune mice that survived virulent Pb-ANKA challenge.

(G) MSP1₁₋₁₉-specific IgG endpoint titers 1 day prior to (pre) and 5 days after (post) virulent Pb-ANKA challenge.

Data (mean \pm SD) in (A)–(D) are representative of three experiments with n = 3–4. Data (mean \pm SD) in (E)–(G) are representative of two independent experiments with n = 3–4 per experimental group (see also Figure S5).

(legend on next page)

parasites (Figure 4). Both PbTII and polyclonal CD4 T cell responses were also skewed toward a more robust T_{FH} phenotype in *P. yoelii*-infected NLRP3-deficient mice, compared to *P. yoelii*-infected WT mice (Figures 7H and 7I). Importantly, *P. yoelii*-immune NLRP3-deficient mice were substantially more resistant to challenge with WT *Pb* ANKA (Figures S6A–S6C), phenotypes that additionally associated with enhanced MBC recall function (Figure S6D). Together, these data provide additional support that NLRP3 activation compromises cDC function and results in suboptimal T_{FH} responses and protective humoral immunity.

Finally, to compare WT and NLRP3 KO cDC1 development and function in the same *Plasmodium*-infected host, we generated and infected WT:NLRP3 KO (50:50) mixed bone-marrow chimeras with Δlap parasites (Figure 7J). Importantly, this approach controls for potential differences in parasite load, antigen, and inflammation in *Plasmodium*-infected WT and KO mice. Although only modest shifts in cDC1:cDC2 ratios were observed among NLRP3 KO cells (Figure 7K), we observed that NLRP3 KO cells exhibited significantly elevated MHC II expression among both total cDC and CD11b^{neg}CD8 α ⁺ cDC1 populations (Figures 7L and 7M), compared to WT cDC and cDC1 populations. These data provide direct *in vivo* evidence that hemozoin-mediated cDC-intrinsic NLRP3 activation, rather than extrinsic and environmental cues that include inflammatory cytokines, such as IL-1 β , regulate the expression of MHC II. Consistent with these findings, NLRP3 KO CD11b^{neg}CD8 α ⁺ cDC1 exhibited significantly enhanced phagocytotic (Figure 7N) and protein processing functions (Figures 7O and 7P), compared to WT cDC1 recovered from the same *Plasmodium* infection environment. Last, to complement these genetic studies and confirm that early NLRP3 activation leads to impaired humoral immunity, we treated Δlap -infected WT mice with MCC950 during the initial stages of DC activation and CD4 T cell priming (days 0 to 6 p.i.) and measured the development of MSP1₁₉-specific plasma cells. Pharmacologic inhibition of NLRP3 inflammasome activity resulted in 2-fold greater numbers of parasite-specific plasma cells by day 28 p.i. (Figures 7Q–7S). Altogether, our data provide direct *in vivo* evidence that hemozoin-mediated inflammasome activation during an initial blood-stage *Plasmodium* exposure limits

cDC1 numbers and functions, which in turn impairs the development of protective anti-*Plasmodium* cellular and humoral immunity.

DISCUSSION

The adaptive immune response elicited by *Plasmodium* infection is robust, but the resilience of humoral memory populations is suboptimal. Waning immune-mediated resistance to malarial disease in individuals who emigrate from endemic areas and the failure of vaccines in endemic populations highlight that new mechanistic understanding of why humoral responses following *Plasmodium* exposure are suboptimal remains a priority. Our study revealed that these defects may be programmed early after an initial *Plasmodium* exposure via hemozoin-mediated, NLRP3 inflammasome-dependent impacts on the cDC compartment with significant reductions in phagocytosis, antigen processing, and MHC II expression occurring as early as day 4 p.i. We further linked these cDC re-programming events to impairments in the stepwise differentiation of T_{FH}, which resulted in reduced GC B cell responses and lower numbers of MBC and LLPC capable of producing protective, anti-parasite antibodies. Further investigation supported that humoral memory is suppressed by DC-intrinsic inflammasome activation. Importantly, hemozoin-induced NLRP3 activation limited humoral immunity irrespective of the strain of parasites (*P. yoelii* or *P. berghei* ANKA) used to initiate cDC reprogramming, suggesting that sustained hemozoin-induced compromise of CD8 α ⁺ cDC numbers and function may be a conserved pathophysiological feature of blood-stage *Plasmodium* infection.

Despite the genetic and life-cycle complexity of *Plasmodium* parasites, hemozoin is currently the only described malaria-associated NLRP3 inflammasome agonist. The capacity for inflammasome activation to alter cDC gene expression and phenotype has been evaluated *ex vivo*, but studies designed to evaluate the contribution of DC-intrinsic inflammasome activation during vaccination and infection are limited. A recent report showed that inflammasome activation during *Salmonella* infection is detrimental to T cell priming and that reduced levels of inflammasome machinery limit splenic DCs from undergoing

inflammasome-mediated pyroptosis (McDaniel et al., 2020). It was further reported that cDC activation by inflammasomes rarely occurs early during infection because of IRF4 and IRF8-mediated suppression of inflammasome genes, but this observation is not consistent with those from the *Plasmodium* field where robust expression of inflammasome genes and caspase 1 activation are observed following both rodent and human infection (Ataide et al., 2014). Indeed, the magnitude of inflammasome activation that occurs during the blood stage of *Plasmodium* infection is supported by high levels of serum IL-1 β , which contribute to malarial symptoms that include fever, chills, and malaise. Deleterious functions for hemozoin during malaria are also suggested by strong correlations between hemozoin accumulation and severe clinical manifestations and inflammation in the central nervous system and placenta, where increased accumulation of monocytes and platelets can exacerbate disease (Hochman et al., 2016; Milner et al., 2013; Moore et al., 2004; Nguyen et al., 1995; Sarr et al., 2006). We found that reducing cDC exposure to hemozoin limited splenic IL-1 β levels by day 10 p.i. and significantly increased DC maturation kinetics and function. Our *in vivo* studies showed that hemozoin-induced, NLRP3-dependent inflammasome activation impaired cDC phagocytosis, antigen processing, and expression of MHC II. Reported discrepancies between experimental studies of *ex vivo* and *in vivo* contributions of inflammasome activation and resultant programming of DC fate and function may be linked to the severity of malaria or virulence of specific species of *Plasmodium* parasites, as well as the tissue-specific deposition and abundance of hemozoin. Our complementary genetic, biochemical, and pharmacologic studies support that NLRP3 activation exerts a similarly deleterious impact on humoral immunity following either *P. yoelii* or *P. berghei* ANKA primary infections.

The functional defects we observed in cDC following hemozoin-mediated NLRP3 inflammasome activation were further linked to negative impacts on the *Plasmodium*-specific T cell response. T cell priming, the emergence of CD150^{lo}CXCR5^{int} T_{FH} precursors, and the eventual differentiation of mature CXCR5^{hi}PD-1^{hi} GC-T_{FH} cells were all reduced by hemozoin-mediated NLRP3 activation in cDC. Notably, alum is a well-documented NLRP3 agonist and adjuvant reported to promote the initiation of T cell and humoral responses. Alum's capacity to dissociate from vaccine components upon injection differs significantly from that of hemozoin, which is retained within the DCs. This difference may serve as one explanation for disparities in reported outcomes following examination of NLRP3-mediated DC function. Our high-resolution analyses revealed that, in the absence of NLRP3 activation, parasite-specific T cells exhibited evidence of enhanced TCR stimulation, which is reported to support increased CXCR5 expression and reinforce T_{FH} differentiation. Whether the presence of hemozoin and altered DC programming impairs a limited number of GC-T_{FH} functions or reduces the expression of multiple co-stimulatory molecules and cytokines is not currently known. Elucidation of the precise mechanisms by which hemozoin limits the capacity of cDC to promote the development of optimal GC-T_{FH} function remains of interest and will also be relevant to our understanding of how *Plasmodium* infection influences responses to either heterologous infection or vaccination.

Our results support the hypothesis that hemozoin and the associated programming of DC number and function contribute to suboptimal humoral responses following *Plasmodium* infection. During a blood-stage *Plasmodium* infection with reduced levels of hemozoin, enhancements in humoral immunity begin early in the spleen, where we observed a coordinated shift in CXCR4⁺CD138⁺ LLPC precursors and accumulation of mature LLPC in the bone marrow. Our data support a model wherein the abundance of LLPC or reactivation of memory B cells mediate protection from lethal parasite challenge, as opposed to either qualitative shifts in either the isotype or affinity of parasite-specific antibodies in mice with reduced hemozoin exposure. Limitations of our study include the sensitivity of assays used to probe the quantity, quality, and functions of secreted antibody responses, particularly in our studies showing enhanced survival yet equivalent immune memory baseline titers in NLRP3 KO mice and WT mice infected with $\Delta pm4\Delta bp2$ parasites. Future molecular and biophysical studies designed to interrogate critical qualitative attributes and effector functions of the secreted antibody responses are warranted. Another notable aspect of our studies that we did not assess is whether hemozoin accumulation within the bone marrow impacts or erodes the maintenance of either vaccine-induced or pathogen-specific LLPC. The bone marrow serves as an infection reservoir for *P. vivax* parasites, and the presence of hemozoin in the bone marrow pushes the cytokine environment toward a more proinflammatory state (Lee et al., 2017). Understanding whether either inflammation or cytokine and chemokine perturbations contribute to reductions in the frequency of mature LLPC following infection with *Plasmodium* may shed light onto additional factors that restrain the quality and/or durability of anti-*Plasmodium* humoral responses.

STAR★METHODS

Detailed methods are provided in the online version of this paper and include the following:

- KEY RESOURCES TABLE
- RESOURCE AVAILABILITY
 - Lead contact
 - Materials availability
 - Data and code availability
- EXPERIMENTAL MODEL AND SUBJECT DETAILS
 - Animals
 - Parasite strains and infections
 - Quantification of parasite biomass
 - Treatments
- METHOD DETAILS
 - Immune cell phenotyping
 - Standard and antibody affinity ELISA
 - ELISPOT
 - IgG purification
 - CTV labeling of T cells
 - *Ex vivo* cultures
 - Phagocytosis assays
- QUANTIFICATION AND STATISTICAL ANALYSIS

STAR★METHODS

KEY RESOURCES TABLE

Reagent or resource	Source	Identifier
Antibodies		
Purified anti-mouse CD3	Biolegend	Cat#100202; RRID: AB_312659
Anti-mouse CD16/32 (Fc-Block)	BioXCell	Cat#BE0307, RRID: AB_2736987
Biotin SP-conjugated Affinipure Goat-anti-IgG (H+L) F(ab)	Jackson Immunoresearch	Cat#112-065-167, RRID: AB_2338179
Purified rat anti-mouse CXCR5	BD Biosciences	Cat#551961, RRID: AB_394302
Anti-mouse CXCR4-BV605 (clone: L276F12)	Biolegend	Cat#146519, RRID: AB_2687359
Anti-mouse CD150-PeCy7 (clone:TC15-12G12.2)	Biolegend	Cat#115914, RRID: AB_439797
Anti-mouse CD267- PE (clone 8F10)	Biolegend	Cat#133403, RRID: AB_2203542
Anti-mouse IgD-PeDazzle 594 (clone: 11-26c.2a)	Biolegend	Cat#405742, RRID: AB_2571985
Anti-mouse CD86-BV605 (clone:GL1)	Biolegend	Cat#105037, RRID: AB_11204429
Anti-mouse CD80-BV510 (clone:16-10A1)	Biolegend	Cat#104741, RRID: AB_2810337
Anti-mouse CD80- PerCPCy5.5 (clone:16-10A1)	Biolegend	Cat#104722, RRID: AB_2291392
Anti-mouse CD11c-PE Cy7 (clone:N418)	Biolegend	Cat#117318, RRID: AB_493568
Anti-mouse CD38-Pac Blue (clone:90)	Biolegend	Cat#102720, RRID: AB_10613468
Anti-mouse CD95-FITC (clone: Jo2)	BD Biosciences	Cat#554257, RRID: AB_395329
Anti-mouse MHCII-AF700 (clone:M5/114.15.2)	Biolegend	Cat#107622, RRID: AB_493727
Anti-mouse CCR6-AF647 (clone:29-2L17)	Biolegend	Cat#129808, RRID: AB_1227497
Anti-mouse CD138 Pac Blue (clone 281-2)	Biolegend	Cat#142523, RRID: AB_2565621
Anti-mouse B220-PerCP-Cy5.5 (clone:RA3-6B2)	Biolegend	Cat#103236, RRID: AB_893354
Anti-mouse B220-PE (clone:RA3-6B2)	Invitrogen	Cat#12-0452-83, RRID: AB_465672
Anti-mouse CD11b-APC (clone: M17/70)	Biolegend	Cat#101212, RRID: AB_312795
Anti-mouse CD4-PerCP-Cy5.5 (clone:GK1.5)	Biolegend	Cat#100434, RRID: AB_893324
Anti-mouse CD8-PerCP-Cy5.5 (clone: 53-6.7)	Biolegend	Cat#100734, RRID: AB_2075238
Anti-mouse CD19-AF700 (clone: 6D5)	Biolegend	Cat#115528, RRID: AB_493735
Anti-mouse CD45.2-PE (clone: 104)	Biolegend	Cat#109808, RRID: AB_313445
Anti-mouse CD273-PE (clone: TY25)	Biolegend	Cat#107206, RRID: AB_2162011
Anti-mouse F4/80-PE (clone: BMB)	Biolegend	Cat#123110, RRID: AB_893486
Anti-mouse Foxp3-PeCy7 (clone: 3G3)	Tonbo	Cat#60-5773-U100, RRID: AB_2621869
Anti-mouse Bcl-6-AF647 (clone IG191E/A8)	Biolegend	Cat#648305, RRID: AB_2565298
Anti-mouse Tbet-BV605 (clone: 4B10)	Biolegend	Cat#644817, RRID: AB_11219388
Anti-mouse CD95-PeCy7 (clone: Jo2)	BD PharMingen	Cat#557653, RRID: AB_396768
Anti-mouse CD73-FITC (clone: TY/11.8)	Biolegend	Cat#127220, RRID: AB_2716076
Anti-mouse PD-1-BV510 (clone: RPM1-30)	Biolegend	Cat#135241, RRID: AB_2715761
Anti-mouse PD-1-FITC (clone: RPM1-30)	Thermo Fisher Scientific	Cat#11998181, RRID: AB_465466
Anti-mouse CD45.1-PacBlue (clone: A20)	Biolegend	Cat#110722, RRID: AB_492866
Anti-mouse CD90.1-PeDazzle (clone: OX-7)	Biolegend	Cat#202524, RRID: AB_1595635
Anti-mouse CD44-AF700 (clone:IM7)	Biolegend	Cat#103026, RRID: AB_493713
Anti-mouse CD44-FITC (clone:IM7)	Biolegend	Cat#103006, RRID: AB_312957
Anti-mouse CD11a-FITC (clone:M17/4)	Biolegend	Cat#101106, RRID: AB_312779
Anti-mouse GL7-FITC (Clone:GL7)	Biolegend	Cat#144603, RRID: AB_2561696
Chemicals, peptides, and recombinant proteins		
Hemozoin	InvivoGen	Cat#tlrl-hz
MCC950 (NLRP3 Inhibitor)	Sigma	Cat#256373-96-3

RESOURCE AVAILABILITY

Lead contact

Further information and requests for resources and reagents should be directed to and will be fulfilled by the Lead Contact, Noah Butler (noah-butler@uiowa.edu).

Materials availability

- This study did not generate unique reagents.

Data and code availability

- All data reported in this paper will be shared by the lead contact upon request.
- This study did not generate/analyze datasets or code.
- Any additional information required to reanalyze the data reported in this paper is available from the lead contact upon request.

EXPERIMENTAL MODEL AND SUBJECT DETAILS

Animals

C57BL/6 wild-type (CD45.2 and CD45.1), C57BL/6-Tg(Nr4a1-EGFP/cre)820Khog/J (Nur77^{GFP} Stock No. 016617) and *Nlrp3*^{tm1Bhk} (NLRP3 KO stock No. 021302) were either purchased from The Jackson Laboratory or acquired from colonies at the University of Iowa. For the generation of WT: NLRP3^{-/-} chimeras, CD45.1 wild-type recipient mice were irradiated with 475 rads twice, separated by 4 h. Bone marrow cells from CD45.1 (C57BL/6) and CD45.2 (NLRP3 KO) were mixed 50:50 and 1×10^7 were injected i.v. Mice were maintained on a Uniprim diet (Envigo) for 2 weeks. Chimerism was assessed at 8 weeks post-irradiation. Age and sex-matched mice between 6 and 13 weeks were used for all experiments. Ethics oversight for animal use was provided by The University of Iowa IACUC.

Parasite strains and infections

Two wild-type *P. berghei* ANKA parasite lines were used: the *Pb*-ANKA line, obtained from MR4 (American Type Culture Collection) and the reporter, reference *P. berghei* ANKA line 676m1c1 (*Pb*-ANKA-Luc), which constitutively express GFP and luciferase that was obtained through BEI Resources (MRA-868) and was contributed by Chris J. Janse and Andrew P. Waters. The *Plasmodium berghei* ANKA mutants $\Delta pm4\Delta bp2$ and Δlap have been described in [Lin et al. \(2015\)](#) and were obtained from Dr. Chris Janse (Leiden University Medical Center, LUMC, the Netherlands). *P. yoelii* (clone 17XNL) were obtained from the Malaria Research and Reference Reagent Resource Center (MR4, American Type Culture Collection). All parasite lines were maintained by passage in NIH Swiss Webster mice. Primary infections were initiated by an intravenous (IV) transfer of 1×10^6 parasitized red blood cells (RBCs) derived from an infected donor mouse. Challenge of mice with virulent *Pb*-ANKA or *Pb*-ANKA-luc were initiated by intravenous (IV) injection of 5×10^6 donor-derived parasitized RBCs.

Quantification of parasite biomass

Percentage of infected RBC was monitored in tail blood samples by flow cytometric analysis of the frequency of Hoechst⁺ Diethylidiumbromide⁺ Ter119⁺ CD45^{neg} cells ([Malleret et al., 2011](#)). Parasite loads, quantified as total flux (p/s/cm²/sr), following IP injection of 250 μ g of D-luciferin (Promega) were determined using an IVIS Lumina S5 and Living Image software (Perkin Elmer).

Treatments

Synthetic hemozoin (sHZ) (InvivoGen; 750 μ g in PBS) was injected every second day IV (tail vein). MCC950 (Sigma, 250 μ g in PBS) was administered via intraperitoneal (IP) injection every 2 days beginning at the time of infection.

METHOD DETAILS

Immune cell phenotyping

For analysis of splenic cells, single cell suspensions were generated by forcing mouse spleens through a 70 μ m mesh. For experiments enumerating cDC subsets, spleens were incubated with collagenase IV (100 U/mL) and DNase I (10 μ g/mL) for 30 mins at 37°C prior to preparation of single cell suspensions. RBC were lysed prior to Fc receptor blockade (CD16/32-clone 2.4G2) in FACS buffer (PBS+ 0.09% sodium azide + 2% FCS) for 15 min at 4°C prior to surface staining. For identifying T_{FH} like cells, cells were stained with purified rat anti-mouse CXCR5 (BD Biosciences) in T_{FH} staining buffer (PBS+ 0.09% sodium azide + 2% FCS+ 0.05% BSA+ 2% mouse serum) for 1h at 4 °C. Cells were washed then stained with biotin-conjugated AffiniPure Goat anti-rat IgG (H+L) (Jackson ImmunoResearch) in T_{FH} buffer for 30 min. Cells were then washed and surfaced stained in an antibody cocktail containing (Anti-CD4, -PD-1, -CD150, -CD11a, -CD44, streptavidin) for at least 30 min at 4°C. Anti-Bcl-6, -T-bet and -Foxp3 (BioLegend) transcription factor staining was performed using the Foxp3 Staining Kit per manufacturer's protocol (BD Biosciences). For B cell staining, cells were surface stained in FACS buffer for at least 30 min in the following cocktail solution containing anti-CD19, -B220, -CD267, -CD138, -CD38 (BioLegend), -CD95 (BD PharMingen), -IgD and -CXCR4 (BioLegend) to identify plasma cells, while a cocktail of anti-CD19, -B220, -CD38, -CD80, -CD273, -CD73, -IgD, -CCR6 (BioLegend) was used to identify memory B cells. cDCs were identified using a surface stain mix containing Anti-CD8, -F4/80, -CD80, -CD86, -CD19, -B220, -CD11c (BioLegend) and anti-CD11b and MHC II (ThermoFisher) following Fc-block for 10 mins at 4°C.

Standard and antibody affinity ELISA

For standard ELISA, Nunc Immunosorb Plates were coated with 1 $\mu\text{g}/\text{mL}$ of recombinant MSP19 overnight at 4°C. Plates were blocked for 2h at RT with PBS+2.5%BSA+ 2%FCS prior to addition of serially diluted sera and incubation overnight at 4°C. Wells were washed with PBS + 0.05% Tween20 prior to incubation with HRP conjugated anti-mouse IgG for 2h at RT. For affinity ELISA, after plates were coated overnight as described above, plates were washed with PBS-Tween prior to blocking with PBS+1% BSA+0.05% Tween for 1h at 37 °C. Diluted serum was incubated for 2h at RT in buffer (2.5% BSA+5% FCS in PBS). Wells were washed extensively with PBS+Tween20 prior to addition of diluted ammonium thiocyanate and incubation for 15 minutes. Wells were washed prior to incubation with HRP conjugated anti-mouse IgG for 1h at 37°C. All plates were reacted with SureBlue TMB Peroxidase and TMB Stop Solution (Sera Care) prior to absorbance measurement at an OD of 450 nm using a plate reader (Biotek). The concentration of serum IL-1 β was assessed using an IL-1 β LEGENDplex immunoassay (Biolegend) according to the manufacturer's protocol.

ELISPOT

White plates (Nunc MaxiSorp) were coated with 1 $\mu\text{g}/\text{mL}$ of recombinant MSP-19 diluted in 0.1M Na₂HPO₄ binding solution and incubated overnight at 4°C. Plates were washed with PBS and blocked for 2h at RT with 10% FCS in RPMI 1640. Bone marrow cells were diluted serially in 10% FCS in RPMI 1640 and incubated for 18 h at 37 °C with 5% CO₂. Plates were thoroughly washed then incubated with HRP-conjugated anti-mouse IgG in PBS+5% FCS overnight at 4 °C. Spots were then developed with 3-amino-9-ethylcarbazole.

IgG purification

The method for IgG purification from immune serum using Protein G Sepharose4 Fast Flow columns was adapted from manufacturer's protocol and Akter et al. (Akter et al., 2019). Briefly, following column equilibration with binding buffer (20 mM sodium phosphate), diluted serum (1:4) was ran over column and flow-through was collected prior to complex elution. IgG was eluted from the column using 0.1M glycine+0.01% sodium azide and the pH was neutralized using 1M Tris-HCl. Amicon Ultra-4 Membrane Units were used for buffer exchange to PBS.

CTV labeling of T cells

CTV labeled CD4+ T cells were prepared according to manufacturer's protocol (Invitrogen) with minor protocol modification. Splenocytes were washed and suspended in serum free media supplemented 1:1000 with Cell Trace Violet. Cells were incubated at 37°C for 20 min prior to dilution with RPMI 1640+10% FCS and incubation for 5 mins. Cells were pelleted and incubated again for 5 mins with RPMI 1640+10% FCS at 37°C prior to surface staining.

Ex vivo cultures

GC-T_{FH} (CXCR5^{hi}PD-1^{hi}) were sort purified from $\Delta pm4\Delta bp2$ - and Δlap -infected mice on day 14 p.i. and suspended in IMDM+10% FCS. Naive B cells, enriched from naive mice using a B cell Isolation Kit (Miltenyi Biotec), were mixed with GC-T_{FH} at a 1:1 ratio and co-incubated for 5 days at 37°C with 5% CO₂. Cell cultures were supplemented with anti-IgM (5 $\mu\text{g}/\text{mL}$) (Jackson ImmunoResearch) and anti-CD3 (5 $\mu\text{g}/\text{mL}$) (Biolegend). For cDC-T cell cultures, magnetically enriched cDCs were pulsed with 1 nM of GP-66 for 1h, washed, and incubated at a 1:10 ratio with CTV-labeled SMARTA cells for 4 days.

Phagocytosis assays

To examine the phagocytic capacity of cDC, splenocyte suspensions were incubated with Fluoresbrite carboxylate microsphere YG (0.5 μm -Polysciences) at a ratio of 1:100 microspheres/cell or in 25 $\mu\text{g}/\text{mL}$ solution OVA-488 (Molecular Probes) for 1h at 37°C. To assess antigen processing by cDC, splenocytes were incubated in a 25 $\mu\text{g}/\text{mL}$ solution of DQ-OVA (Molecular Probes) for 1h at 37°C. Cells were then stained with Fc-block for 10 mins at 4°C prior to surface staining.

QUANTIFICATION AND STATISTICAL ANALYSIS

Data centers in summary data graphs represent the mean. Data dispersion and tests of statistical significance are detailed in the figure legends. Graphs were generated and statistical analyses were performed using Prism Graphpad 9 software (GraphPad Software). For analyses comparing only two groups, Mann-Whitney non-parametric tests were used to determine p value. For comparison of 3 or more groups, Dunn's test for nonparametric multiple comparisons were employed and adjusted P values are reported. Details can be found in respective figure legends.
