#### Propositions that belong to the dissertation:

### Contemplations into Respiration: Effects of breathing and meditative moment on body and mind

#### Roderik Gerritsen

- 1. Slow breathing exercises with extended exhalations increase parasympathetic activity levels acutely; they relax.
- Some resting state heart rate variability measures (HRV) are valid indicators of tonic vagal tone, but they are only reliable in specific contexts.
- 3. There is an association between vagal tone HRV and cognitive (control) functioning, but this relationship is correlational.
- 4. Respiratory vagal nerve stimulation (rVNS) is a promising construct, by describing the relationship between respiratory patterns, the autonomic nervous system and cognition.
- Tai Chi Chuan is an easy way to increase functional balance in aging populations. However, when the aim is cognitive enhancement, its (short term) effectiveness is doubtful.
- 6. Much like HRV, BRV, or breath rate variability, could be an informative marker of the physical and mental flexibility of human beings.
- 7. Bayesian statistics is an invaluable scientific tool in truth finding, by virtue of evidence loading, and should completely replace classical statistics.
- 8. Sample size matters.
- 9. In contemplative science, questions and hypotheses tend to mingle with hopes and beliefs.
- 10. Cognitive science should start thinking outside of the black box.
- By machine learning various autonomic state markers can be pattern recognized into the individual *autonome*, making personalized approaches (mental) health possible.
- 12. Artificial general intelligence is only possible when digital systems breathe.
