Behorende bij het proefshrift
The lexico-semantic representation of words in the mental lexicon
te verdedigen op dinsdag 25, September, 2025
aan de Universiteit Leiden door

Yufang Wang

1. Native Mandarin Chinese speakers exhibit sensitivity to animacy violations, indicating that animacy plays a crucial role in word production.
2. A greater number of overlapping semantic features leads to increased spreading of activation during lexical access in Mandarin Chinese.
3. When producing a bare noun, multiple compatible classifiers are activated with the degree of activation being determined by their corresponding compatibility with the given noun.
4. The mental lexicon encodes lexico-syntactic features for a noun as a probabilistic distribution.
5. The Jensen-Shannon divergence (JSD) can serve as a generalized metric of lexico-syntactic congruency in paradigms like picture-word interference, offering a quantitative lens on compatibility.
6. Corpus analyses suggest that classifiers usage in Mandarin Chinese can be modeled as a probability distribution for each noun.
7. Since holistic and decompositional accounts of semantic memory are non-mutually exclusive, it remains a challenge to experimentally tease apart these theories.
8. Accessing bare nouns is influenced not only by semantic content but also by their embedded lexico-syntactic features.
9. Accounting for the classifier distribution will make computational language models of Mandarin more accurate.
