### **General introduction**

## PREFACE

Proteins, nucleic acids and polysaccharides are the macromolecules of life. Throughout the birth, growth and death of the cell, these macromolecules interact with each other to ensure propagation of messages not only within the cell but also between cells. For instance, proteins, which represent about 15% of a cell in mass, are the workhorses of the cell. Protein-protein interactions are involved at each and every step of cellular events, such as DNA/RNA synthesis and degradation, protein synthesis, folding and degradation, signal transduction (within the cell and between cells), regulation of protein activity, and immune response.

Therefore, understanding protein-protein interactions is essential to understand the processes that occur in the cell, and ultimately to develop cures for the deficient processes.

The PhD research presented here aims at characterizing the molecular details of the interaction between a protein involved in copper homeostasis (CCS<sup>1</sup>) and the neuronal adaptor X11 $\alpha$ , originally discovered by McLoughlin *et al.* (McLoughlin *et al.*, 2001).

Some background information about copper homeostasis and the role of chaperones will first be provided. Next, general features of X11 proteins domains will be discussed. Finally, the work presented in this thesis will be outlined.

---

<sup>1</sup> CCS: copper chaperone for superoxide dismutase 1 (see pg. 117 for a complete list of abbreviations)

Figure 1.1: **A.** Schematic representation of the role of CCS. The extracellular divalent copper (white circle  $\text{Cu}^{2+}$ ) is reduced to  $\text{Cu}^+$  (green circle) and then enters the cell via a membrane-bound copper transporter (in white). Inside the cell, the copper is taken up by CCS, which delivers it to the target, resulting in an active SOD1. **B.** Schematic representation of the situation in the presence of the neuron protein X11 $\alpha$ . CCSIII (in dark blue) binds the PDZ2 domain of X11 $\alpha$  (in dark pink) and transfer of copper to SOD1 can no longer occur, resulting in an inactive SOD1.

## I.1 - COPPER HOMEOSTASIS

Metals are involved in many essential biological reactions. Necessary as they are, they are also potentially toxic for cells and must therefore be carefully handled.

In the last decade it has been discovered that cells are equipped with an elaborate system of transport for copper, so that free copper ions are virtually absent inside the cell (Rae *et al.*, 1999). For instance, *Saccharomyces cerevisiae* possesses repeated DNA sequences (named CuREs) at the promoter region of the genes coding for the membrane copper transporters Ctr1, Ctr3 and Fre1. These repeats are the target of a nuclear sensor protein specific for copper ions (Mac1) that detects the amount of copper available (Labbe *et al.*, 1997). At low copper concentration, Mac1 binds the CuREs and the expression of the transporters is activated (Yamaguchi-Iwai *et al.*, 1997; Jensen *et al.*, 1998; Martins *et al.*, 1998; Joshi *et al.*, 1999). Under higher copper level, Mac1 undergoes conformational changes so that it is released from the CuREs and the production of the membrane transporters is terminated (Labbe *et al.*, 1997).

Divalent copper, Cu(II), present outside the cell is reduced to Cu(I) by iron-containing membrane proteins Fre1 and Fre2 (Dancis, 1998; Martins *et al.*, 1998), illustrating in addition a tight coupling between copper and iron homeostasis. Cu(I) is allowed then to cross the membrane by the action of high-affinity transporters (see Figure 1.1), Ctr1 and Ctr3 (Dancis *et al.*, 1994; Knight *et al.*, 1996; Pena *et al.*, 2000). Once inside the cell, metallochaperones shuttle the copper ions to their target proteins. There exists a specific chaperone for each target, and each compartment within the cell possesses its own chaperone-target system. The chaperone Cox17 brings copper to the mitochondrial cytochrome c oxidase (Glerum *et al.*, 1996) involved in respiration. Atx1 carries it to the high-affinity iron transporter Fet3 via the membrane bound Ccc2 protein at the Golgi apparatus (Lin *et al.*, 1997; Pufahl *et al.*, 1997), and CCS shuttles copper to the SOD1 (superoxide dismutase 1) (Culotta *et al.*, 1997), an enzyme involved in removal of reactive oxygen species (ROS) (Harrison *et al.*, 1999; Pena *et al.*, 1999; O'Halloran and Culotta, 2000).

This system of Cu transport is conserved across many life forms, as homologues of the above mentioned yeast chaperones have been identified in bacteria, plants,

worms and mammals (Culotta *et al.*, 1997; Klomp *et al.*, 1997; Himelblau *et al.*, 1998; Nishihara *et al.*, 1998; Wakabayashi *et al.*, 1998; Hiromura and Sakurai, 1999; Lockhart and Mercer, 2000; Hiromura *et al.*, 2000; Wong *et al.*, 2000; Solioz *et al.*, 2003; Silahatoglu *et al.*, 2004).

Impairment in the physiological function of one of the proteins involved in copper transport, or in the target protein has been related to neurodegenerative disorders. For example, amyotrophic lateral sclerosis (ALS) is caused by mutations resulting in an inactive SOD1 (Goto *et al.*, 2000). Menkes and Wilson's diseases are associated with copper shortage and excess, respectively, due to malfunctioning of Ccc2 homologues (Waggoner *et al.*, 1999).

## **I.2 - THE COPPER CHAPERONE FOR SUPEROXIDE DISMUTASE 1**

Three domains have been identified in CCS (Lamb *et al.*, 1999; Rosenzweig *et al.*, 1999) as depicted in Figure 1.1. The N-terminal domain (CCSI) exhibits high homology with ATX1 (mentioned above), and hence was named ATX1-like domain. It is supposed to bind Cu(I). The central domain (CCSII) resembles the target SOD1, hence the name SOD1-like domain; it is believed to be involved in target recognition. Finally, the C-terminal domain of the human CCS (CCSIII) consists of 40 residues and contains a Cys-X-Cys motif, suggested to bind Cu(I) (Falconi *et al.*, 1999; Rosenzweig and O'Halloran, 2000).

As mentioned above, CCS is essential for SOD1 activation (Culotta *et al.*, 1997). Surprisingly, it has been shown that CCSII and CCSIII, but not CCSI, are necessary for copper loading into SOD1 *in vivo*. CCSI is required only under copper starvation conditions (Schmidt *et al.*, 1999; Schmidt *et al.*, 2000).

The role of CCSIII remained unclear until crystal structures of the yeast homologue of CCS were solved. Comparative studies of the structure of the native CCS alone and in complex with SOD1 (Lamb *et al.*, 1999; Lamb *et al.*, 2001) provided some clues about the mechanism of copper delivery between CCS and SOD1. Those structures

revealed that the SOD1-like domain of CCS binds the target, and that CCSIII adopts a well-defined conformation in the complex with its two cysteines positioned close to the copper binding site of SOD1, while it was disordered and not observed in the structure of the native CCS. Furthermore, the structures show that the copper binding domain (ATX1-like) of CCS is too far from the target site of SOD1 for direct interaction. It was therefore suggested (Falconi *et al.*, 1999; Rosenzweig and O'Halloran, 2000) that the flexible CCSIII serves as a shuttle between the copper binding site of the ATX1-like domain of CCS and that of SOD1.

Also, a new partner of CCS was discovered in brain cells. McLoughlin *et al.* demonstrated that the human CCS and X11 $\alpha$ , a neuronal protein related to Alzheimer's disease, interact via their third domain (CCSIII) and second PDZ<sup>2</sup> domain (PDZ2 $\alpha$ ), respectively (McLoughlin *et al.*, 2001). Consequently, SOD1 cannot acquire copper, and it fails to fulfill its essential physiological role (see Figure 1.1).

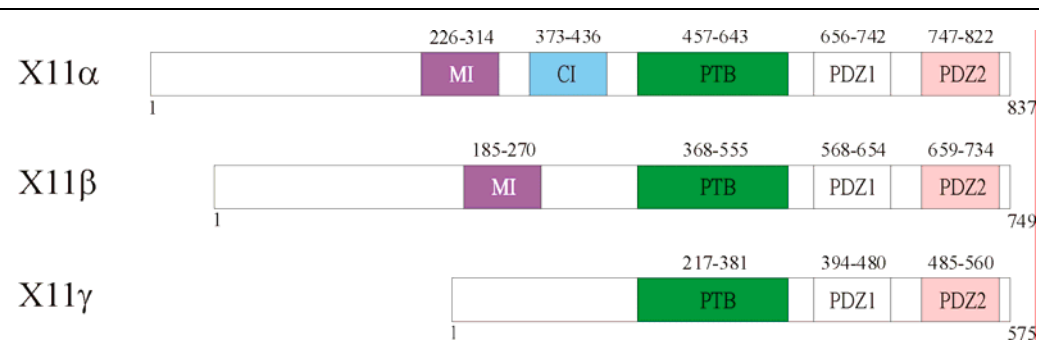

## I.3 - THE NEURONAL ADAPTOR FAMILY X11

### I.3.1 - General aspects

X11 proteins, also known as Mint proteins (for Munc18 interacting protein), are so-called adaptor proteins. They contain multiple domains (see Figure 1.2) able to recruit proteins, resulting in the formation of large protein complexes as shown in Figure 1.3. The X11 family counts three members:  $\alpha$ ,  $\beta$  and  $\gamma$  (Swiss-Prot accession number Q02410, Q99767 and O96018, respectively). X11 $\alpha$  and  $\beta$  are expressed only in the brain, while X11 $\gamma$  is expressed ubiquitously (Okamoto and Sudhof, 1997; Okamoto and Sudhof, 1998).

---

<sup>2</sup> PDZ: post-synaptic density-95 protein, Drosophila disks-large protein A, zona occludens protein

**Figure 1.2:** Schematic representation of the organization of the three X11 family members

All three contain a PTB (*p*hospho*t*yrosine *b*inding domain) and two PDZ domains, the role of which is explained below. The main differences are observed in the N-terminal domains: X11 $\gamma$  lacks the MI domain (*M*unc18a *i*nteracting *d*omain) present in the other two homologues. The function(s) of X11 protein(s) is(are) still a matter of debate and varies depending on the organism of study (Biederer *et al.*, 2002).

The cartoons of Figure 1.3 show the organization and the various partners of all three X11 proteins known to date.

**Figure 1.3:** Scheme of the various partners of the three X11 family members ( $\alpha$ ,  $\beta$  and  $\gamma$ ). See text for further explanations

### *1.3.2 - The PTB domain*

The PTB domain is present in all three X11s. It binds the C-terminal domain of the amyloid precursor protein (APP) (Biederer *et al.*, 2002; Ho *et al.*, 2002) with the protection of cellular APP against degradation as a result, and a reduction of the production and the secretion of A $\beta$  (the major component of the senile plaques and fibrils present in the brains of Alzheimer patients).

### *1.3.3 - The N-terminal domains (Nt)*

X11 $\alpha$  and  $\beta$  interact with Munc18a via their MI moiety (Okamoto and Sudhof, 1997; Ho *et al.*, 2002). Co-expression of Munc18a and any of the three X11s modulates the protective role of X11s against APP degradation. The presence of Munc18a suppresses the secretion of A $\beta$ 40 (one degradation product of APP) even more than in the presence of X11 alone. Surprisingly, the protective effect of X11 $\gamma$  on APP is also enhanced by the presence of Munc18a, although X11 $\gamma$  (which lacks the MI domain) is not able to interact directly with Munc18a.

X11 $\alpha$  can also form a complex with CASK (another adaptor protein) via its unique CI domain. Simultaneously, CASK binds Veli (yet another family of adaptors). The formation of this trimer is believed to be the starting point of protein assembly at the synaptic junction for exocytosis and neurotransmission (Butz *et al.*, 1998).

The N-terminal part (Nt) of X11 $\beta$  has been shown to bind a protein located on the endoplasmic reticulum (XB51), inhibiting the above-mentioned A $\beta$ 40 secretion suppressor role of X11 $\beta$  (Lee *et al.*, 2000).

### *1.3.4 - The conserved PDZ domains*

The functions of the two PDZ domains of X11s are still unclear. They seem to possess an unusual number of partners (as compared to other PDZ domains).

All three X11s have been shown to bind presenilins (the only protein known to date to be responsible for inherited Alzheimer) via either or both PDZ domains (Biederer *et al.*, 2002). The authors suggest that the enzymatic activity of presenilins (involved

in the degradation of APP) be inhibited when presenilins are in complex with X11s and APP together (and maybe more proteins).

X11 $\alpha/\beta$  have been shown to bind neurexins (involved in neuronal exocytosis) via their PDZ domains (although it is not clear which one) (Biederer and Sudhof, 2000). The purpose of this interaction is thought to bring Munc18a at the synaptic membrane, where it is required for signal transmission.

The most N-terminal PDZ domain of X11 $\alpha$  has been shown to interact with the carboxy-terminus of the presynaptic Ca<sup>2+</sup> voltage-gated channel (Maximov *et al.*, 1999). The authors suggest that this interaction occurs in the presence of the above-mentioned trimer X11/CASK/Veli for neurotransmission.

In addition to its suppressing role of A $\beta$ 40 secretion mentioned earlier, X11 $\beta$  has been suggested to regulate the production of A $\beta$ 42 (another degradation product of APP) at the endoplasmic reticulum (Tomita *et al.*, 2000). Indeed, they have demonstrated that the second PDZ domain of X11 $\beta$  binds the transcription factor NF- $\kappa$ B/p65, repressing the expression of enzymes responsible for APP cleavage into A $\beta$ 42.

Furthermore, the C-terminal PDZ domain of X11 $\alpha$  (as mentioned above) has been reported to interact with the third domain of CCS (McLoughlin *et al.*, 2001), suggesting a new role for X11 $\alpha$  and PDZ domains.

## I.4 - PDZ DOMAINS

### I.4.1 - Roles

PDZ domains are present in a large number of proteins, often involved in signal transduction. Their role is to help the formation of protein complexes, usually at the plasma membrane, but also in the nucleus (for reviews see (Fanning and Anderson, 1999; Jelen *et al.*, 2003; van Ham and Hendriks, 2003). Despite a low sequence similarity among the PDZ domains, their structures are remarkably conserved, consisting of six  $\beta$ -strands and two  $\alpha$ -helices (see Figure 1.4).

**Figure 1.4:** General fold of PDZ domains. The  $\beta$ -strands are annotated  $\beta A$  to  $\beta F$ ; the  $\alpha$ -helices are annotated  $\alpha A$  and  $\alpha B$ . The white arrow represents the canonical ligand with the carboxy-terminal group at the tip of the arrow.

#### 1.4.2 - Modes of interaction and classification

The classical binding of the carboxy-terminal tail of partner proteins to PDZ domains occurs in a binding pocket located between  $\beta B$  and  $\alpha B$ , creating an extension of the existing  $\beta$  sheet (see Figure 1.4). This interaction site consists of conserved residues situated in the L1 loop and the  $\beta B$  strand. It contains a conserved sequence motif (G/Q-L-G-F/I) on the PDZ domain and a conserved arginine N-terminal of this motif that is involved in coordination of the carboxy-terminus of the target via a water molecule. The interacting peptides have traditionally been grouped into four classes on the basis of their C-terminal sequences: Class I contains S/Tx $\Phi^*$  sequences (where  $\Phi$  corresponds to any hydrophobic residue and  $*$  to the

carboxy terminus), Class II contains  $\Phi_x\Phi^*$ , Class III E/D $\times\Phi^*$  and Class IV V $\times$ D/E\* sequences (Vaccaro and Dente, 2002). It is now well documented that PDZ domains are promiscuous, able to bind C-termini across classes (Palmer *et al.*, 2002; Walma *et al.*, 2002). PDZ domains are also capable of recognizing internal peptide motifs through the same binding groove (Hillier *et al.*, 1999), such as displayed by the interaction between the second PDZ domain of  $\alpha$ 1-syntrophin and the C-terminal  $\beta$ -finger of nitrous oxide synthase (NOS). Furthermore, PDZ domains have other interaction surfaces (Feng *et al.*, 2002; Feng *et al.*, 2003; Im *et al.*, 2003), and not only proteins but also phospholipids may serve as binding targets (Zimmermann *et al.*, 2002).

As a response to the increase in the variety of partners, new classifications of PDZ are regularly published. Bezprozvanny and Maximov (Bezprozvanny and Maximov, 2001) suggest two positions in PDZ domains as determining their binding specificities. 'Pos1' is the first residue after the  $\beta$ B strand, and 'Pos2' is the first residue in the  $\beta$ A helix. The authors have determined 5 groups for Pos1 and five groups for Pos2, giving a total of 25 PDZ classes. However, the limited experimental data allows to find examples for only 9 out of the 25 classes. In a more recent attempt to classify PDZ domains, Kang *et al.* define three sites in the PDZ domains ( $S_0$ ,  $S_{-1}$  and  $S_{-2}$ ) (Kang *et al.*, 2003a) where the last 3 carboxy-terminal residues of the peptide ligand bind ( $P_0$ ,  $P_{-1}$  and  $P_{-2}$  corresponding to the last, penultimate and antepenultimate residues, respectively). The authors determine five groups of PDZ-ligand complexes depending on the combination of occupied S sites by the ligand. These combinatorial models even include models for non C-terminal ligands.

Finally, this classification is supported and extended by the observations made by Walma, which led to a new system of classification (Walma, 2004). She showed that two classes are distinguishable, depending on the solvent accessibility of only one residue in the ligand,  $P_{-1}$ , giving an unprecedented importance to that residue in PDZ-ligand complex formation. When  $P_{-1}$  is highly buried (>80%) in the PDZ domain upon binding, the ligand is called a P1 type of ligand. When  $P_{-1}$  is less buried (<75%), the ligand is a P2 type. For each type of ligand, specific regions in the PDZ fold were identified that interact with the residues of the ligand up to  $P_{-3}$  (see

Table 1.1). Namely, P<sub>-1</sub> residues of the P1 type of ligand make contact with residues at the C-terminus of  $\beta$ C and L1, while the P<sub>-1</sub> residues of P2 types of ligand interact with only one residue at the N-terminus of the  $\beta$ B strand. Furthermore, the P<sub>-2</sub> residues of P1 type of ligands do not show specific interactions with their PDZ partners, while the P<sub>-2</sub> residues of P2 type of ligands show interactions with residues placed in the  $\alpha$ B helix of the PDZ domain. Finally, the P<sub>-3</sub> residues of P1 type of ligands interact with the N-terminus of the  $\beta$ B strand, while the P<sub>-3</sub> residues of P2 type of ligand make contact with the C-terminus of  $\beta$ B and N-terminus of the  $\alpha$ B helix.

Table 1.1: Typical interaction of PDZ domain regions with the P<sub>-1</sub>, P<sub>-2</sub> and P<sub>-3</sub> residues of P1 and P2 types of ligands.

	P1 type of ligand	P2 type of ligand
P <sub>-1</sub> residue	C-terminus of $\beta$ C strand, loop L1	N-terminus of $\beta$ B strand
P <sub>-2</sub> residue	-	$\alpha$ B helix
P <sub>-3</sub> residue	N-terminus of $\beta$ B strand	C-terminus of $\beta$ B strand, N-terminus of $\alpha$ B helix

In another view, PDZ domains are not considered isolated items within the protein. Rather, they appear to be working in tandem. The rationale behind this phenomenon is not yet understood. Some studies report a cooperative mechanism, while others show that a combination of PDZ domains improves the stability of their three dimensional folds (Grootjans *et al.*, 2000; Feng *et al.*, 2003; Long *et al.*, 2003), although this does not seem to be universal (Kang *et al.*, 2003b).

## I.5 - OVERVIEW OF THIS THESIS

The goal of this research was to examine the interaction between the third domain of the human CCS (CCSIII) and the second PDZ domain of X11 $\alpha$  (PDZ2 $\alpha$ ).

Among the 40 residues of the human CCSIII, there are two potential binding sites, one at the C-terminus, and the other in the middle of CCSIII. The C-terminal sequence of human CCSIII (AQPPAHL) only partially fits the class II consensus sequence (see section I.4.2), as the antepenultimate P<sub>-2</sub> residue of CCSIII does not contain the large hydrophobic residue but an alanine instead. Alternatively, the residues G<sup>248</sup>LTIWEER<sup>255</sup> of CCSIII could present an internal interaction motif in analogy of the syntrophin-NOS complex.

Using high-resolution NMR spectroscopy the structural basis of the interaction between CCSIII and PDZ2 $\alpha$  was examined. The resonance frequencies of most <sup>1</sup>H, <sup>15</sup>N and <sup>13</sup>C nuclei of PDZ2 $\alpha$  were determined (Chapter 2). These were then used to solve the structure of PDZ2 $\alpha$  in solution (Chapter 3). We then explored the binding of the C-terminal and internal CCSIII sequence motifs, and interpreted the results using the structure of PDZ2 $\alpha$  (Chapter 4).

The results presented so far were done on a tagged protein. Ideally, one would prefer to work on untagged protein for the type of research that has been done here. Thus, the possibility of separating tags from a protein of interest with a new generation of proteases, Pd compounds, was investigated. The results are reported in Chapter 5.

In Chapter 6, a general discussion of the results is provided.

## Chapter II

**$^1\text{H}$ ,  $^{13}\text{C}$ , and  $^{15}\text{N}$  assignment of the second PDZ domain  
of the neuronal adaptor protein X11 $\alpha$**

## II.1 - INTRODUCTION

Copper is an important cofactor of a number of proteins involved in essential biological reactions. As copper ions are highly reactive in solution, nature has devised systems to avoid free copper ions in the cell (Rae *et al.*, 1999). One example of such a system is the couple CCS–SOD1. CCS presumably takes the  $\text{Cu}^+$  from one of the copper transporters at the plasma membrane and brings it to the cytoplasmic SOD1 (Culotta *et al.*, 1997). A functional CCS is necessary for SOD1 to acquire  $\text{Cu}^+$  and be active. McLoughlin *et al.* have demonstrated that CCS can interact with a neuron protein (X11 $\alpha$ ) via their C-terminal (CCSIII) and second PDZ domains (PDZ2 $\alpha$ ), respectively (McLoughlin *et al.*, 2001), with an inactive SOD1 as a result.

X11 $\alpha$  is a so-called adaptor protein; via its various domains, it forms multi-protein complexes that are involved in signal transduction and cellular communication (Okamoto and Sudhof, 1997; Butz *et al.*, 1998; Biederer *et al.*, 2002; Ho *et al.*, 2002).

PDZ domains are commonly described as cellular glues, enhancing the formation of complexes of proteins involved in signal transduction (Fanning and Anderson, 1999; van Ham and Hendriks, 2003).

In view of the above-mentioned interaction between CCSIII and PDZ2 $\alpha$ , McLoughlin *et al.* suggest a new role for X11 $\alpha$  and PDZ domains.

The above mentioned interaction between PDZ2 $\alpha$  and CCSIII constitutes thus a new type of interaction. Determination of the structure of PDZ2 $\alpha$  and of its complex with (part of) CCSIII may give new insights into how the interaction between X11 $\alpha$  and CCS affects the loading of SOD1 with copper. The first step toward structure calculation by NMR is the assignment of the NMR spectra of PDZ2 $\alpha$ , which is presented in this chapter.

## II.2 - MATERIALS AND METHODS

### II.2.1 - Protein expression and purification:

The sequence coding from residue 745 to 823 of X11 $\alpha$  (corresponding to our residues 12 to 90) (see Figure 2.1) was cloned by PCR from human brain cDNA into a pET3H expression vector (Chen and Hai, 1994), resulting in a construct with an N-terminal poly-histidine tag and 6 additional residues (LETMGN) in front of the original PDZ sequence. The gene was over-expressed in *E.coli* BL21 (DE3\*RP) grown at 28°C. For full isotope labeling, M9 minimal medium was supplemented with  $^{15}\text{NH}_4\text{Cl}$  (0.5 g/L) and uniformly labeled  $^{13}\text{C}$ -glucose (3 g/L) (CIL, Andover MA) as sole sources of nitrogen and carbon. For the purpose of stereospecific assignment, M9 minimal medium was supplemented with  $^{15}\text{NH}_4\text{Cl}$  (0.5 g/L), 10% uniformly labeled  $^{13}\text{C}$ -glucose (0.5 g/L) and 90% unlabeled glucose (4.5 g/L) (Senn *et al.*, 1989). When the  $\text{OD}_{600}$  of the culture reached 0.6, expression was induced by adding 0.5 mM IPTG and incubation was continued for 11 hours. After centrifugation, the cell pellet of 1 L of culture was resuspended in 10 ml 20 mM Tris-HCl pH 8.0 and kept at -80°C until the next step. After thawing, the cells were sonicated in the presence of 1 mM PMSF and 0.1% NP-40 (a non-ionic detergent). The lysate was brought to 0.5 M NaCl prior to centrifugation at 30,000 g for 1 hour. The supernatant was then loaded onto a Hi-Trap Chelate resin (Pharmacia) saturated with nickel and eluted with an imidazole gradient (0 to 400 mM in 20 mM Tris, 0.5 M NaCl, pH 8.0). The eluted fractions were analyzed on 15% PAA Tris/Tricine/SDS gel. Those exhibiting a single band on the gel below 14 kDa were pooled and dialyzed extensively against MilliQ grade water. Precipitates were removed by centrifugation for 10 minutes at 4500g.

### II.2.2 - NMR spectroscopy:

For NMR analysis the purified PDZ2 $\alpha$  domain was concentrated by evaporation in a centrifuge under vacuum to ca. 2.2 mM in 250  $\mu\text{l}$  and brought to 10 mM sodium phosphate buffer pH 6.7. A deuterated sample was obtained (where the labile protons were exchanged for deuterium) by a series of concentrations-dilutions in

D<sub>2</sub>O; subsequently, the sample was brought to 10 mM sodium phosphate buffer (in D<sub>2</sub>O) pH 6.7 (uncorrected for deuterium effect). Sequence specific assignments of  $^{13}\text{C}_\alpha$ ,  $^{13}\text{C}_\beta$ ,  $^{13}\text{CO}$ ,  $^{15}\text{N}$  and HN were obtained from HNCACB, HNCO and HN(CA)CO experiments. Aliphatic assignments for the side chains were obtained from H(CCCO)NH, CCCONH, CCH and HCCH-TOCSY experiments. This set of spectra was recorded on a Bruker DMX 600 MHz spectrometer at 290K equipped with a TXI-Z-GRAD ( $^1\text{H}$ ,  $^{15}\text{N}$ ,  $^{13}\text{C}$ ) probe. The data were processed using the Azara 2.7 suite of programs, provided by Wayne Boucher and the Department of Biochemistry, University of Cambridge (available at [www.bio.cam.ac.uk](http://www.bio.cam.ac.uk)). They were further analyzed with Ansig for Windows (Helgstrand *et al.*, 2000). The aromatic carbons and protons were assigned from CBCDHD and CBCDHE spectra. Stereospecific assignments of valine and leucine side chain methyls were obtained from  $^{13}\text{C}$ -CT-HSQC experiments using a 10%  $^{13}\text{C}$ -labeled sample brought to a concentration of 2.5 mM in 250  $\mu\text{l}$ .

This set of data was recorded on a Varian Unity Inova 600 at 290 K and was processed with NMRPipe suite (Delaglio *et al.*, 1995) (see <http://spin.niddk.nih.gov/bax/software/NMRPipe/>).

## II.3 - RESULTS

### II.3.1 - Purification of PDZ2 $\alpha$

The PDZ2 $\alpha$  domain consists of a six-histidine-tag, followed by an engineered linker of six residues (LETMGN), and then residues 745 to 823 of the original X11 $\alpha$  sequence (corresponding to residues 12 to 90 in our numbering – see Figure 2.1 and the Material and Methods section of this chapter).

**Figure 2.1:** Sequence of the PDZ2 $\alpha$  construct. The numbers in bold correspond to the Swiss-Prot numbering (accession code Q02410). The numbers in italics correspond to the numbering used throughout this manuscript. The underlined bold residues indicate the conserved arginine coordinating the ligand via a water molecule, and the conserved binding motif.

The purification of PDZ2 $\alpha$  is straightforward. One step of nickel-IMAC (Immobilized Metal Affinity Chromatography) suffices to eliminate almost all contaminating *E.coli* proteins. The remaining contaminants precipitate during dialysis against MilliQ water (see Figure 2.2) and are removed by centrifugation, leading to a fraction of PDZ2 $\alpha$  over 95 % pure. One liter of bacterial culture in M9 minimal medium yield about 10 mg of PDZ2 $\alpha$ .

**Figure 2.2:** Purification of PDZ2 $\alpha$ . (1) Soluble fraction of *E.coli* after sonication and centrifugation; (2) Non-binding fraction; (3) Fraction of non specifically bound proteins, eluted at 30 mM imidazole; (4) Fraction of specifically bound proteins, eluted at 120 mM imidazole; (5) Soluble PDZ2 $\alpha$  after dialysis against water; (6) Insoluble fraction after dialysis; (7) Standard molecular weight marker. The molecular masses are indicated at the right hand side of the gel in kDa.

*II.3.2 - Extent of assignment and data deposition*

The  $^{15}\text{N}$ -HSQC spectrum of PDZ2 $\alpha$  at pH 6.7 and 290 K is shown in Figure 2.3. The backbone  $^1\text{H}$ ,  $^{15}\text{N}$ ,  $^{13}\text{C}_\alpha$  and  $^{13}\text{CO}$  have been completely assigned except for the N-terminal His-tag, Leu 6 and Pro 67. All aliphatic side chain protons have been fully assigned except for Leu 75. All protonated  $^{13}\text{C}$  and  $^{15}\text{N}$  resonances are available except for some histidine aromatic rings (H53, H68, H73 and H83), the side chain methyls of methionines (M9, M39, M84 and M87). Of all arginines in the PDZ2 $\alpha$  sequence, only the  $^{15}\text{N}_\epsilon$ 's of Arg 19 and 54 were determined.

**Figure 2.3:** 600 MHz  $[^{15}\text{N},^1\text{H}]$ -HSQC spectrum of 2.2 mM uniformly  $^{13}\text{C}$ ,  $^{15}\text{N}$ -labeled PDZ2 $\alpha$  in 10mM sodium phosphate buffer pH 6.7 at 290K. Resonances are labeled with residue type and sequence number. Side chain amides (sc) are connected by solid lines.

Chemical Shift Index analysis (Wishart and Sykes, 1994) suggests the presence of 4  $\beta$ -strands (residues 12-18, 28-30, 55-58, and 82-87) and 2  $\alpha$ -helices (residues 43-46, and 68-76) in PDZ2 $\alpha$  (see Figure 2.4). This prediction is in agreement with the known structures of other PDZ domains.

**Figure 2.4:** Secondary structure prediction of PDZ2 $\alpha$  based on the chemical shift index (CSI) (Wishart and Sykes, 1994).

The assignments as presented in Table 2.1 have been deposited at the BMRB, under accession number 6113.

The assignment list is sufficiently complete to proceed with structure determination protocols (see Chapter 3).

**Table 2.1:** Assignment table of PDZ2 $\alpha$

## Chapter III

### Structure determination of the second PDZ domain of the neuronal adaptor X11 $\alpha$ by NMR

Partially published as Duquesne A.E, de Ruijter M., Brouwer J., Drijfhout J.W., Nabuurs S.B., Spronk C.A.E.M., Vuister G.W., Ubbink M. and Canters G.W (2005) *J. Biomol. NMR*, in press.

**ABSTRACT**

X11 $\alpha$  is a neuron specific multidomain protein involved in protein-protein interactions that mediate signal transduction and cellular communication. A new partner for X11 $\alpha$  was discovered, the copper chaperone for superoxide dismutase 1 (CCS), by McLoughlin *et al.* (McLoughlin *et al.* (2001) *J. Biol. Chem.*, **276**, 9303-9307). The interaction was shown to involve the second PDZ domain of X11 $\alpha$  (PDZ2 $\alpha$ ) and the third domain of CCS (CCSIII). In order to study the details of this interaction, the structure of PDZ2 $\alpha$  was determined with high-resolution NMR spectroscopy. PDZ2 $\alpha$  adopts the canonical PDZ fold with six  $\beta$ -strands and two  $\alpha$ -helices. Two special distinguishing features involve the two loops flanking the  $\beta$ B strand: the N-terminal loop is longer while the C-terminal loop is shorter when compared with other known PDZ structures.

### III.1 - INTRODUCTION

PDZ domains are commonly referred to as cellular glues. They are present in a large number of proteins, often involved in signal transduction. Their role is to help the formation of protein complexes, usually at the plasma membrane (Fanning and Anderson, 1999; van Ham and Hendriks, 2003). The interaction between the second PDZ domain of X11 $\alpha$  (PDZ2 $\alpha$ ) and the third domain of the copper chaperone for superoxide dismutase (CCSIII) discovered by McLoughlin *et al.* (McLoughlin *et al.*, 2001) suggests a new additional role for PDZ domains.

Despite a low sequence similarity among the PDZ domains, their 3D-structures, consisting of six  $\beta$ -strands and two  $\alpha$ -helices, appear remarkably conserved.

The aim of the study is to shed light on the mechanisms of interaction between PDZ2 $\alpha$  and CCSIII. The work presented here describes the structure of PDZ2 $\alpha$ . The structure was solved by using multidimensional high-resolution NMR spectroscopy.

### III.2 - MATERIALS AND METHODS

#### III.2.1 - Protein expression and purification:

The cloning of the PDZ2 $\alpha$  sequence and expression and purification protocols have been described in the Materials and Methods section of Chapter 2.

#### III.2.2 - NMR spectroscopy:

For NMR analysis the purified PDZ2 $\alpha$  domain was concentrated by evaporation in a centrifuge under vacuum to ca. 1.2 mM in 250  $\mu$ l and brought to 10 mM sodium phosphate buffer pH 6.7. The distance restraints were obtained from 3D  $^{15}$ N-NOESY-HSQC and  $^{13}$ C-NOESY-HSQC spectra, recorded on a Varian Unity Inova 800 MHz spectrometer at 290 K, all with a mixing time of 100 ms. The data were processed with the NMRPipe suite (Delaglio *et al.*, 1995) (<http://spin.niddk.nih.gov/bax/software/NMRPipe/>) and analyzed with CARA

(Keller, 2004) (available at <http://www.nmr.ch/>). The  $T_1$ ,  $T_{1\rho}$  and  $\{^1\text{H}\}$ - $^{15}\text{N}$  NOE experiments were recorded on a Varian Unity Inova 600 MHz spectrometer at 290 K. The relaxation delays for the  $^{15}\text{N}$ - $T_1$  experiment were 0.016, 0.096, 0.192, 0.512, 0.768 and 1.024 s. For the  $^{15}\text{N}$ - $T_{1\rho}$  experiment they were 0.016, 0.032, 0.048, 0.064, 0.080 and 0.112 s.

### III.2.3 - Structure calculation:

The NOE cross-peak assignments and a consistent tertiary fold were obtained from the automated iterative assignment program CANDID (Herrmann *et al.*, 2002), which works in conjunction with three-dimensional structure calculations in the program CYANA (Guntert *et al.*, 1997). The calculations consisted of the standard protocol of seven cycles of iterative NOE assignments and structure calculations (Herrmann *et al.*, 2002). In each of the seven cycles the NOEs assigned by CANDID were supplemented by the backbone dihedral angle constraints obtained from chemical shift analysis using the program TALOS (Cornilescu *et al.*, 1999).

The final structure calculations with CYANA were started from 100 conformers with random torsion angle values. Simulated annealing with 10,000 time steps per conformer was done using the CYANA torsion angle dynamics algorithm (Guntert *et al.*, 1997). Using the FormatConverter, developed as part of the Collaborative Computing Project for the NMR Community (CCPN) (Fogh *et al.*, 2002), the distance and dihedral angle restraints were converted to the X-PLOR (Brünger, 1992) restraint format. Subsequently the 100 generated structures were refined using a short restrained molecular dynamics simulation in explicit solvent (Linge *et al.*, 2003; Nabuurs *et al.*, 2004) in the program XPLOR-NIH (Schwieters *et al.*, 2003). Of these, the 20 lowest energy structures were selected to form the final ensemble.

The quality of the structure ensembles was judged both by their agreement with the experimental restraints and the quality scores as determined by the structure analysis programs PROCHECK (Laskowski *et al.*, 1993) and WHAT\_CHECK (Vriend, 1990). Averages and standard deviations were calculated from the checks of the individual members of the final ensemble. The coordinates have been

deposited at the Protein Data Bank, accession code 1Y7N. All figures were made using the program YASARA (<http://www.yasara.org/>) except for Figures 3.1B and 3.1C which were made with the program Molmol (Koradi *et al.*, 1996).

### III.3 - RESULTS

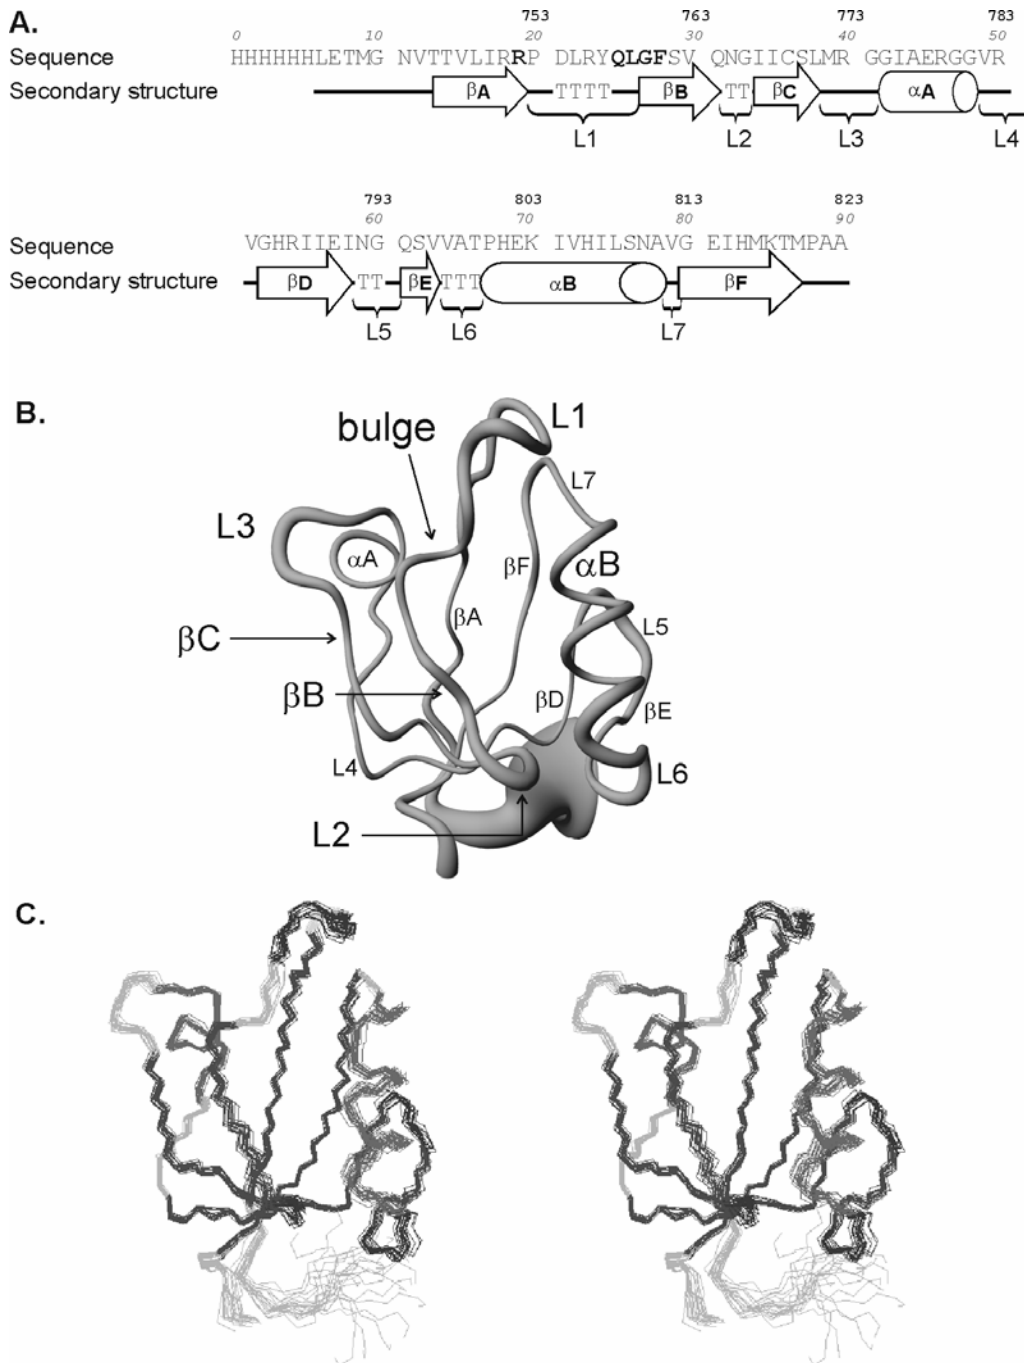

#### III.3.1 - Structure of PDZ2 $\alpha$

The solution structure of the second PDZ domain of X11 $\alpha$  (PDZ2 $\alpha$ ) was solved using high-resolution multi-dimensional heteronuclear NMR. The PDZ2 $\alpha$  construct consisted of a six-residue histidine-tag, a non-native engineered linker of six residues (LETMGN), followed by residues 745 to 823 of the original X11 $\alpha$  sequence (corresponding to residues 12 to 90 in our numbering – see Figure 3.1A and the Material and Methods section of Chapter 2). The protein was obtained using the protocol described in Chapter 2. Near-complete assignments of  $^1\text{H}$ ,  $^{15}\text{N}$  and  $^{13}\text{C}$  spectra were obtained (see Table 2.1) using standard procedures.

On the basis of 1690 NOE-derived distance constraints and 95 dihedral restraints (see Table 3.1) an ensemble of NMR structures was calculated using the torsion-angle dynamics protocol. A tube representation and a stereoview of the ensemble encompassing residues 7 to 90 are shown in Figures 3.1B and 3.1C, respectively. The ensemble of models has been submitted to the Protein Data Bank (accession code 1Y7N). As expected, the first 6 residues (comprising the His-tag) are not represented because no data were obtained for these residues from the NMR experiments. The ensemble was analyzed using the programs PROCHECK (Laskowski *et al.*, 1993) and WHAT IF (Vriend, 1990), and the structural statistics are reported in Table 3.1. The average pairwise RMSD of the ordered backbone heavy atoms (using residues 14 to 87) is  $0.50 \pm 0.10 \text{ \AA}$ , while the average pairwise RMSD of the global backbone heavy atoms is  $1.02 \pm 0.26 \text{ \AA}$ , indicating a well-defined ensemble, even in the loop regions. The Ramachandran analysis displays 90.3% of the residues in the most

favored region, and an additional 9.2% in the allowed regions. The average RMS Z-scores are close to 1, indicating a good covalent geometry of the ensemble.

The ensemble displays a compact fold formed of six  $\beta$ -strands ( $\beta$ A to  $\beta$ F), two  $\alpha$ -helices ( $\alpha$ A and  $\alpha$ B), 3 loops and 4  $\beta$ -turns (L1 to L7) packed in the characteristic PDZ fold. The conserved arginine of the peptide binding motif is situated in the loop L1 and the consensus binding motif is between the loop L1 and the  $\beta$ -strand  $\beta$ B. As expected, the groove for ligand interaction, formed by the second  $\beta$ -strand ( $\beta$ B) and the second  $\alpha$ -helix ( $\alpha$ B), is also present in PDZ2 $\alpha$ . Sequence and structural alignment with the third PDZ domain of Psd-95 (PDB code 1BE9 (Doyle *et al.*, 1996)) and the second PDZ domain of PTP-BL (PDB code 1GM1 (Walma *et al.*, 2002)) (see Figures 3.2A and 3.2B) shows two unique features for the PDZ2 $\alpha$  ensemble. First, the loop L1, connecting the first and the second  $\beta$ -strand, is longer by two residues (Leu 22 and Arg 23), forming a cap above the binding groove. Although this L1-loop is longer, the position of the consensus binding motif (QLGF) remains structurally unchanged at the border between L1 and the second  $\beta$ -strand ( $\beta$ B), allowing the residues Leu 26 and Gly 27 to form the bulge typical for PDZ domains. Second, the loop L2, situated between the second and the third  $\beta$ -strand, consists of only two residues (Asn 32 and Gly 33). It is six to ten residues shorter when compared to most other PDZ domains. However, the positions of the secondary structure elements with respect to each other are not perturbed. Figure 3.2B shows that the strands  $\beta$ C to  $\beta$ F and the helix  $\alpha$ B align properly on top of their homologues in the other two PDZ domains. Only the helix  $\alpha$ A does not align well with its homologue in 1BE9 and 1GM1. The enlargement presented in Figure 3.2C shows the side chains of the conserved residues among the three superimposed PDZ domains. The Arg 19 backbone of PDZ2 $\alpha$  does not overlap very well with its homologues in the other two PDZ domains because it is situated at the start of the loop L1. However, the side chain of Arg 19 overlaps well with its homologues, pointing inside the binding groove. In the binding motif, three out of four residues (Leu 26, Gly27 and Phe 28) are oriented in a similar way as their homologues in the other two PDZ domains. Only the first residue (Gln 25 in PDZ2 $\alpha$ ), which is present at the end of loop L1, appears to have different orientations in all three PDZ domains.

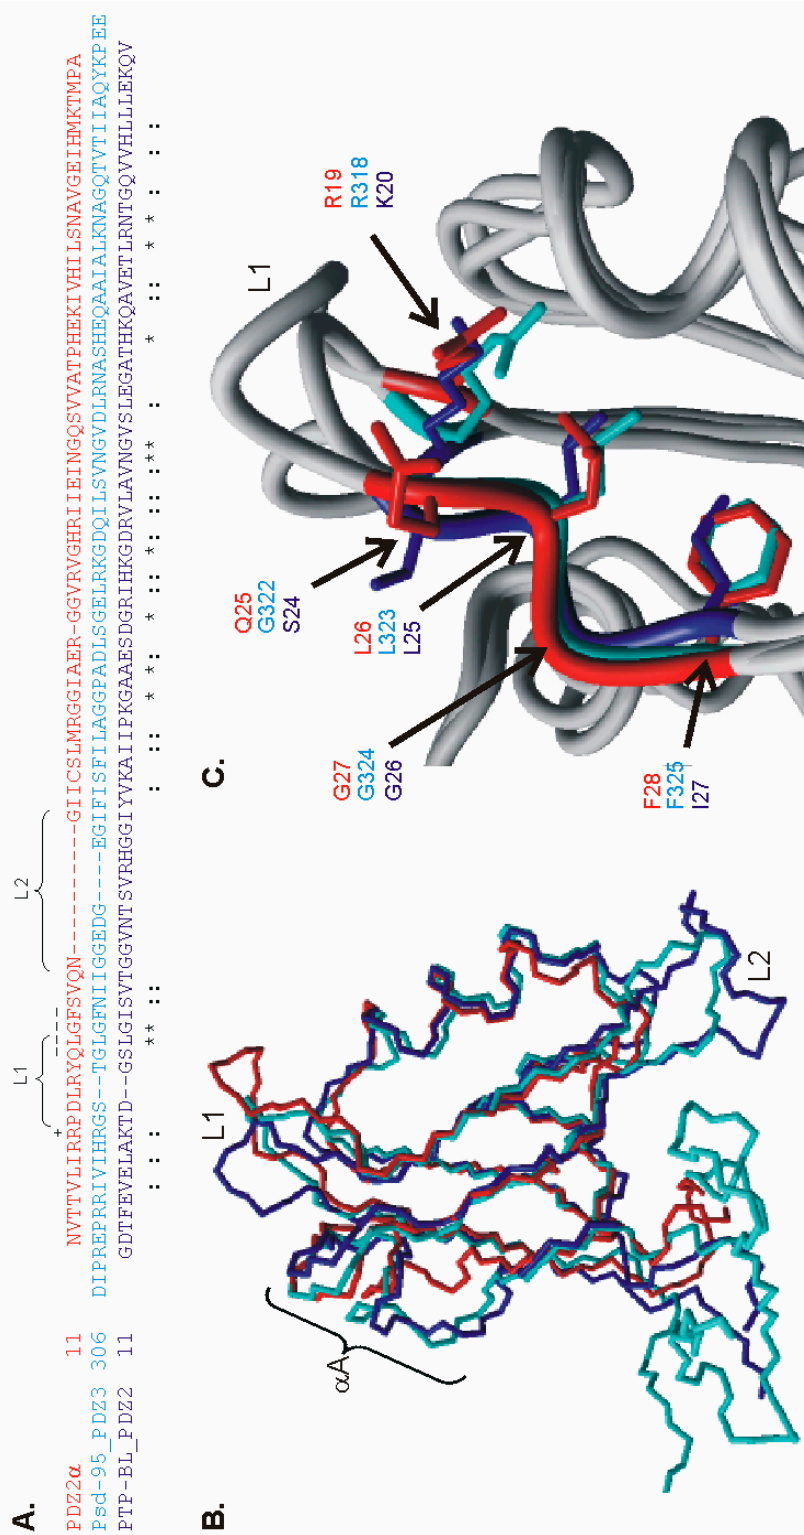

**Figure 3.1:** **A.** Sequence of the PDZ2 $\alpha$  construct. The numbers in bold correspond to the Swiss-Prot numbering. The numbers in italics correspond to the numbering used throughout this paper. The residues in bold indicate the conserved arginine (R19) coordinating the ligand via a water molecule in other PDZ-peptide complexes, and the conserved binding motif (Q25 to F28). The secondary structure elements of PDZ2 $\alpha$  are shown below the sequence. T indicates residues in  $\beta$ -turns; **B.** Tube representation of an ensemble of 20 superimposed models of PDZ2 $\alpha$ . The diameter of the tube represents the RMSD of the backbone atoms in the ensemble; **C.** Stereoview of the same PDZ2 $\alpha$  ensemble as in B. The  $\alpha$ -helices, the  $\beta$ -strands and the  $\beta$ -turns are indicated in dark.

### III.3.2 - Dynamics

$^{15}\text{N}$  relaxation experiments ( $\{^1\text{H}\}$ - $^{15}\text{N}$  NOE,  $^{15}\text{N}$ - $R_1$  and  $^{15}\text{N}$ - $R_{1\rho}$ ) were recorded on PDZ2 $\alpha$ . The resulting data were used to calculate the overall tumbling rate ( $\tau_c$ ), the internal correlation time ( $\tau_e$ ) and the order parameters ( $S^2$ ) using the model-free approach (Lipari and Szabo, 1982a; Lipari and Szabo, 1982b) (see Figure 3.3) as implemented in the program Modelfree 4.01 (Mandel *et al.*, 1995). Prolines 20, 67 and 88, valine 49 and isoleucines 58 and 71 were not taken into account (because of spectral overlap for the latter three). The overall tumbling rate of PDZ2 $\alpha$  is described by an isotropic model with an average global correlation time of  $7.1 \pm 0.8$  ns, which is a typical value for such a small, folded protein at 290 K. The local motion of 38 residues is described by a model incorporating only the  $S^2$  parameter, 31 residues by a model requiring both  $S^2$  and  $\tau_e$  parameters, and 3 residues by a model with motions on the pico- and sub-nanosecond time scales as described by the  $S^2$ ,  $S^2_{\parallel}$  and  $\tau_e$  parameters. Four residues, Arg 19, Val 64, Ala 65 and Thr 66, require a model incorporating chemical exchange, as is also evident from their increased  $R_{1\rho}$  relaxation rates. Interestingly, Arg 19 is the conserved residue involved in coordinating a bridging water molecule in the peptide binding pocket. Residues Val 64, Ala 65 and Thr 66 are located in the loop L6, connecting  $\beta\text{E}$  and  $\alpha\text{B}$ . Flexible residues, displaying more pronounced motion on the ps-ns timescale are found at the N-terminal part of  $\beta\text{A}$ , the loops L1, L3, L7 and part of  $\beta\text{F}$  of PDZ2 $\alpha$ .

**Figure 3.3:**  $^{15}\text{N}$  relaxation data (NOE,  $R_1$  and  $R_{1\rho}$ ) and results of the model-free analysis are plotted for all residues. The secondary structure elements are indicated at the bottom.

### III.4 - DISCUSSION

The ensemble of 20 superimposed models shows a well-defined structure of PDZ2 $\alpha$ . Although the sequence conservation of different PDZ domains is rather low (24% similarity and 14% identity – see Figure 3.2A), the PDZ fold is conserved in PDZ2 $\alpha$ , with six  $\beta$ -strands and two  $\alpha$ -helices.

The structural alignment with the third PDZ domain of Psd-95 (PDB code 1BE9 (Doyle *et al.*, 1996)) and the second PDZ domain of PTP-BL (PDB code 1GM1 (Walma *et al.*, 2002)) revealed two special features of PDZ2 $\alpha$  (see Figures 3.2B): the loop L1 is longer and the loop L2 is shorter. However, the arrangement of the rest of the secondary structural elements with respect to each other is maintained. The conserved residues (Arg 19, Leu 26, Gly 27 and Phe 28) are properly positioned for ligand binding (see Figure 3.2C).

## Chapter IV

### **Binding characteristics between the second PDZ domain of X11 $\alpha$ and the third domain of CCS.**

Partially published as Duquesne A.E, de Ruijter M., Brouwer J., Drijfhout J.W., Nabuurs S.B., Spronk C.A.E.M., Vuister G.W., Ubbink M. and Canters G.W (2005) *J. Biomol. NMR*, in press.

**ABSTRACT**

X11 $\alpha$  is a neuron specific multidomain protein that interacts with the copper chaperone for superoxide dismutase 1 (CCS) (McLoughlin *et al.* (2001) *J. Biol. Chem.*, **276**, 9303-9307). The authors have demonstrated that the interaction occurs between the second PDZ domain of X11 $\alpha$  (PDZ2 $\alpha$ ) and the third domain of CCS (CCSIII). Two potential binding sites on CCSIII can be distinguished: an internal sequence (G<sup>248</sup>LTIWEER<sup>255</sup>) and the C-terminus of CCSIII (AQPPAHL). The interaction was studied by chemical shift perturbation analysis. NMR spectra of the PDZ2 $\alpha$  were compared in the absence and in the presence of one of the two peptides mentioned above. No interaction with the internal sequence was observed, while the C-terminal peptide of CCSIII interacts with PDZ2 $\alpha$  with a dissociation constant of 91  $\mu$ M. The results also show that CCSIII does not directly interact with PDZ2 $\alpha$  beyond the antepenultimate (P-2) residue of CCSIII (Ala 272).

## IV.1 - INTRODUCTION

PDZ domains are cellular glues. Their role is to help the formation of protein complexes, usually at the plasma membrane (Fanning and Anderson, 1999; van Ham and Hendriks, 2003). Despite a low sequence similarity among the PDZ domains, their structures are remarkably conserved, consisting of six  $\beta$ -strands and two  $\alpha$ -helices. The classical binding of the carboxy-terminal tail of ligand proteins to PDZ domains occurs in a binding pocket located between  $\beta$ B and  $\alpha$ B, creating an extension to the existing  $\beta$  sheet. This interaction involves a conserved sequence motif (G/Q-L-G-F/I) on the PDZ domain and a conserved arginine N-terminal of this motif that is involved in coordination of the carboxy-terminus of the target via a water molecule. The interacting peptides have traditionally been grouped into four classes on the basis of their C-terminal sequences: Class I involves S/Tx $\Phi^*$  sequences ( $\Phi$ : hydrophobic residue; \*: carboxy terminus; x: any residue), Class II involves  $\Phi$ x $\Phi^*$ , Class III E/Dx $\Phi^*$  and Class IV VxD/E\* sequences (Vaccaro and Dente, 2002). It is now well documented that PDZ domains are promiscuous, and are able to bind C-termini across classes (Palmer *et al.*, 2002; Walma *et al.*, 2002). PDZ domains are also capable of recognizing internal peptide motifs through the very same binding groove (Hillier *et al.*, 1999), such as displayed by the interaction of the second PDZ domain of  $\alpha$ 1-syntrophin and the C-terminal  $\beta$ -finger of nitrous oxide synthase (NOS). Furthermore, PDZ domains have other interaction surfaces (Feng *et al.*, 2002; Feng *et al.*, 2003; Im *et al.*, 2003), and not only proteins but also phospholipids serve as binding targets (Zimmermann *et al.*, 2002).

Among the 40 residues of the human CCSIII, there are two potential binding sites, one at the C-terminus, and the other in the middle of CCSIII. The C-terminal sequence of human CCSIII (AQPPAHL) only partially fits the class-II consensus sequence, as the antepenultimate P<sub>-2</sub> residue of this motif usually comprises a large hydrophobic residue, instead of the current alanine. Alternatively, the residues G<sup>248</sup>LTIWEEER<sup>255</sup> could present an internal interaction motif in analogy of the syntrophin-NOS complex.

We have investigated the binding modes between PDZ2 $\alpha$  and the two peptides of CCSIII mentioned above, and determined which of the two interacts with PDZ2 $\alpha$ . For this purpose, NMR chemical shift perturbation analysis was performed, comparing the backbone resonances of PDZ2 $\alpha$  in the absence of any peptide and in the presence of increasing amounts of the peptides. The analysis of the presence/absence of resonance shifts provides information about the residues of PDZ2 $\alpha$  involved in peptide binding as well as kinetic data.

## IV.2 - MATERIALS AND METHODS

### *IV.2.1 - Protein expression and purification:*

The cloning, expression and purification protocols of PDZ2 $\alpha$  were described in the Materials and Methods section of Chapter II.

### *IV.2.2 - Peptide synthesis:*

Synthetic peptides were prepared by solid phase technology on a Syro II peptide synthesizer (MultiSyntech, Witten, Germany) at 10  $\mu$ mol scale. TentagelS AC or AM resins (Rapp, Tübingen, Germany) were used in combination with Fmoc-protected amino acids carrying TFA-labile side chain protecting groups where needed (Fields and Noble, 1990). Acylations were carried out with a six-fold excess of amino acid using PyBOP/NMM activation in NMP. Deprotection was performed with piperidine/NMP 1/4 (v/v). Cleavage of the peptides and removal of the side chain protecting groups was performed with TFA/water 19/1 (v/v) for 2.5 h at room temperature. Peptides were precipitated with ether/pentane 1/1 (v/v), washed extensively with this mixture and air-dried. Peptides were dissolved in HOAc/water 1/9 (v/v) and lyophilized overnight. RP-HPLC analysis indicated >90% purity and mass spectrometric analysis (Maldi-Tof, Voyager DE Pro, Perseptive Biosystems, Framingham, USA) confirmed the expected molecular masses.

The peptide sequences were as follows: AQPPAHL, Ac-AQPPAHL, Ac-AQPPAHL-NH<sub>2</sub>, Ac-AQPPAHA, Ac-AQPPAAL, Ac-AQPAAHL, and Ac-GLTIWEER-NH<sub>2</sub>, wherein 'Ac-' indicates an acetylated N-terminus and '-NH<sub>2</sub>' indicates an amidated C-terminus.

#### IV.2.3 - NMR spectroscopy:

For the titration experiments, a solution of the PDZ2 $\alpha$  domain was concentrated to 1 mM in 500  $\mu$ l and brought to 10 mM sodium phosphate buffer pH 6.7. Spectra were recorded on a Bruker DMX 600 MHz spectrometer at 290 K equipped with a TXI-Z-GRAD (<sup>1</sup>H, <sup>13</sup>C, <sup>15</sup>N) probe. 2D <sup>1</sup>H,<sup>15</sup>N-HSQC spectra were recorded at each titration point. The data were processed using the Azara 2.7 suite of programs (available at [www.bio.cam.ac.uk/azara](http://www.bio.cam.ac.uk/azara)) and were further analyzed with Ansig for Windows (Helgstrand *et al.*, 2000).

#### IV.2.4 - Peptide titration:

Each peptide was dissolved in 10 mM sodium phosphate buffer 5% D<sub>2</sub>O, and the pH was brought to 6.7 by adding concentrated NaOH. The concentrations of the peptide solutions were measured by NMR with 1D single scan experiments. The area under the leucine or alanine methyl resonances was integrated and compared with that of a known standard. Binding curves were obtained by plotting the chemical shift difference ( $\Delta\delta^{15}\text{N}$ ) of the backbone nitrogen of the most affected residues against the corresponding peptide:protein ratio (R). The dissociation constant (K<sub>D</sub>) was derived by global fitting with the following equation (Kannt *et al.*, 1996) in the programme Origin 7.5 (OriginLab Corporation, Northampton, MA):

$$\Delta\delta = \frac{\Delta\delta_{\max} \left( T - \sqrt{T^2 - 4R} \right)}{2},$$

where

$$T = 1 + R + \frac{K_D \left( [R * A] + B \right)}{A * B},$$

A is the starting concentration of PDZ2 $\alpha$ , B the concentration of the stock solution of peptide, and  $\Delta\delta_{\max}$  the  $\Delta\delta$  at  $R \rightarrow \infty$ .

The average chemical shift values ( $\Delta\delta_{\text{avg}}$ ) were calculated by using the following equation derived (Garrett *et al.*, 1997):

$$\Delta\delta_{\text{avg}} = \sqrt{\frac{\left(\frac{\Delta\delta^{15}N}{5}\right)^2 + (\Delta\delta^1H)^2}{2}},$$

where  $\Delta\delta^{15}N$  and  $\Delta\delta^1H$  are the chemical shift differences for the backbone nitrogen and proton of a given residue, respectively.

### IV.3 - RESULTS

To test the interactions between PDZ2 $\alpha$  and CCSIII, the two potential interaction motifs of CCSIII were examined. Peptide 1, derived from the original residues 248 to 255 of CCSIII, consisted of the sequence Ac-GLTIWEER-NH<sub>2</sub>, where Ac- and -NH<sub>2</sub> correspond to the neutralizing acetyl- and amide- groups, respectively. Peptide 2 corresponds to the last seven residues at the C-terminus of CCSIII with a modified N-terminal alanine (Ac-AQPPAHL). Each peptide was titrated into a solution of 1 mM of PDZ2 $\alpha$ , and the binding was followed by NMR. At each titration point, a 2D <sup>1</sup>H,<sup>15</sup>N-HSQC spectrum of <sup>15</sup>N-labeled PDZ2 $\alpha$  was recorded.

#### IV.3.1 - Ac-GLTIWEER-NH<sub>2</sub>

Figure 4.1A shows the superposition of two spectra of PDZ2 $\alpha$ . The black trace corresponds to the signal of the free domain, and the red trace corresponds to that of PDZ2 $\alpha$  in the presence of 22.4 equivalents of Ac-GLTIWEER-NH<sub>2</sub>. Each circle corresponds to the resonance of a backbone nitrogen and its proton. Addition of Ac-GLTIWEER-NH<sub>2</sub> to PDZ2 $\alpha$  only resulted in very small chemical shift perturbations

in the HSQC spectrum at high peptide to protein ratio, from which it was concluded that no specific interaction occurred.

#### *IV.3.2 - Ac-AQPPAHL*

Ac-AQPPAHL corresponds to the C-terminal residues of CCSIII. The N-terminal group of this peptide is rendered neutral by converting it to an acetyl group ("Ac-"). The spectrum of the domain at each titration point (18 in total) was recorded by NMR. Figure 4.1B shows the overlay of 7 of these titration points. In contrast with the results obtained with the previous peptide, many resonances in the NMR spectrum PDZ2 $\alpha$  exhibit a clear chemical shift perturbation upon addition of the Ac-AQPPAHL peptide, indicating a specific interaction between the peptide and the protein. Resonances with small perturbations remain visible during the entire titration, while others are broadened at the same peptide:protein ratio due to an intermediate exchange regime. At 20:1 peptide:protein ratio all resonances, with exception of Leu 26, reappear, indicating near-complete saturation of the protein with peptide.

**Figure 4.1:** **A.** Overlay of  $^1\text{H},^{15}\text{N}$ -HSQC spectra of PDZ2 $\alpha$  in the absence (black) and in the presence (red) of 22.4 equivalents of Ac-GLTIWEER-NH<sub>2</sub> to the protein; **B.** Chemical shift perturbation of PDZ2 $\alpha$  upon addition of Ac-AQPPAHL. The overlaid spectra correspond to the following titration points: 0.0, 0.05, 0.3, 0.6, 1.0, 4.0, and 20.0 equivalents of peptide to protein. The direction of the perturbation is indicated by an arrow.

From the chemical shift perturbations, the dissociation constant ( $K_D$ ) of PDZ2 $\alpha$  for Ac-AQPPAHL was determined to be  $91 \pm 2 \mu\text{M}$  (see Figure 4.2).

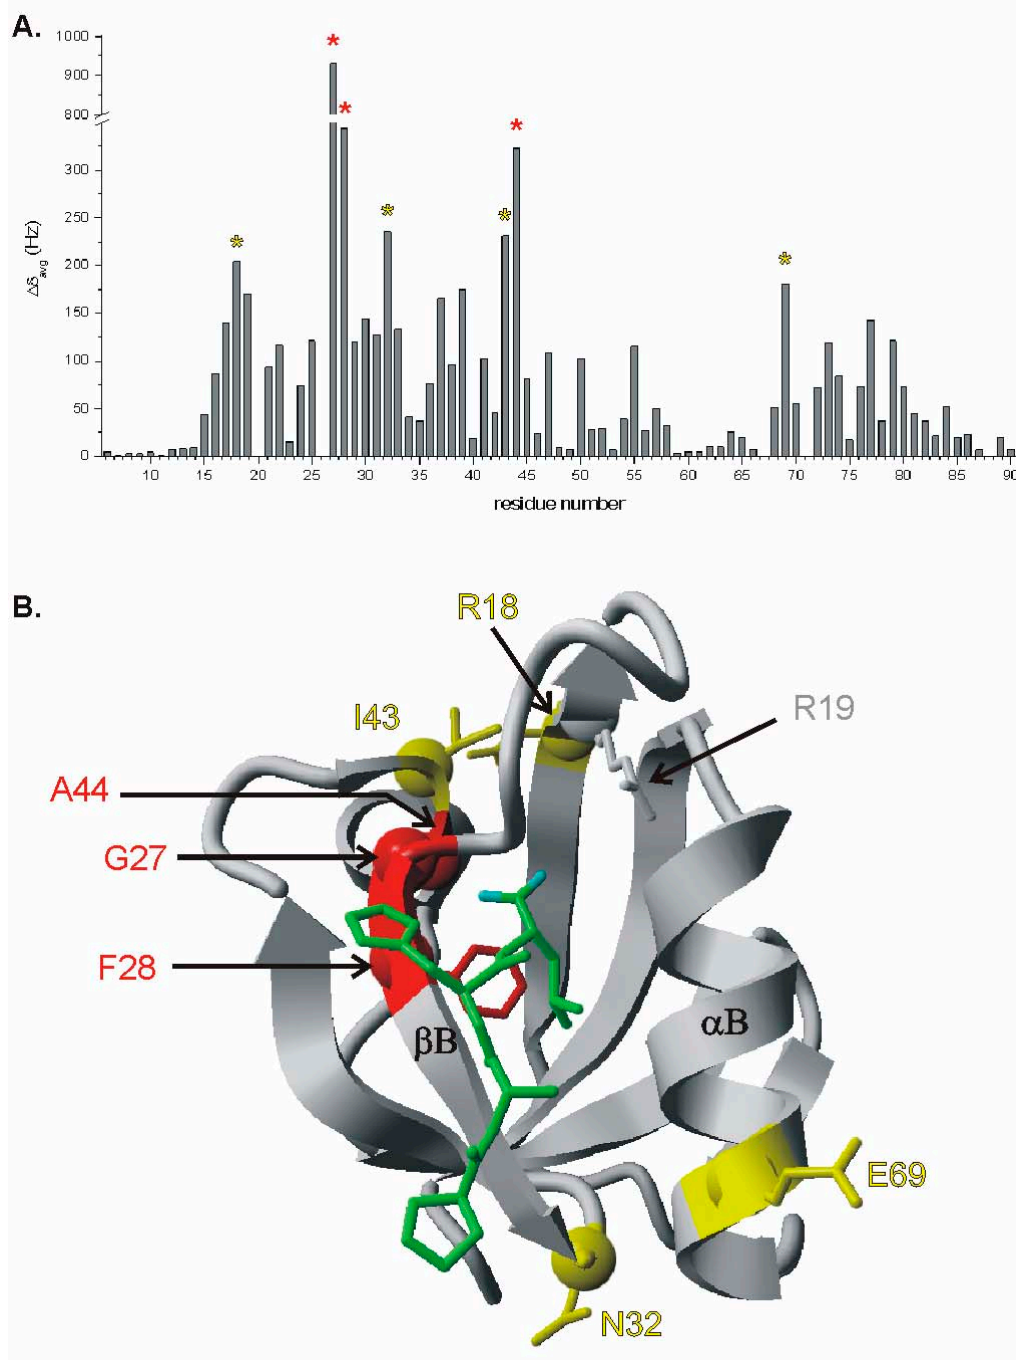

**Figure 4.2:** Titration curves derived from the backbone nitrogen chemical shift perturbation of E57, K70, and V79 upon addition of Ac-AQPPAHL.

Figure 4.3A shows the maximum average shift ( $\Delta\delta_{\text{avg}}$ ), averaged over the nitrogen and proton perturbation for all PDZ2 $\alpha$  backbone amides, in the presence of 20 equivalents of Ac-AQPPAHL. The residues experiencing the largest perturbation have been grouped in two classes, according to the size of the perturbation. The three most affected residues are Gly 27 and Phe 28 of the canonical binding motif (as expected), and Ala 44. Four more residues are strongly affected by the binding of Ac-AQPPAHL: Arg 18, Asn 32, Ile 43 and Glu 69. As mentioned above, the extensive broadening of Leu 26 indicates that it must be among the most perturbed residues. However, the broadening precludes determination of the perturbation size.

All seven residues have been mapped onto the backbone of PDZ2 $\alpha$  (see Figure 4.3B). The picture also shows the last four residues of the peptide (PAHL) modeled

---

in PDZ2 $\alpha$  on the basis of the PSD-95-peptide complex (PDB accession code 1BE9 (Doyle *et al.*, 1996)). The model was obtained by structural alignment of PDZ2 $\alpha$  and PAHL with the third PDZ domain of the synaptic protein PSD-95 bound to its peptide. The largest effects observed are corroborated by the presence of the last two residues of the peptide (His and Leu) in the close vicinity of Gly 27 and Phe 28. The effect observed on Ala 44 seems to be only indirect. Also for residues Arg 18 and Ile 43, it is unlikely that the peptide directly interacts with them. As for residues Asn 32 and Glu 69, they are situated at the bottom of the groove forming the binding pocket. The Pro seems to be close to residue Asn 32 of PDZ2 $\alpha$ , both side chains stacking on top of each other. However, the distance between the proline side chain of the peptide and residue Glu 69 of PDZ2 $\alpha$  is too large for direct interaction.

**Figure 4.3:** **A.** Histogram representation of the maximum average chemical shift perturbation ( $\Delta\delta_{avg}$ ) in the presence of 20 equivalents of Ac-AQPPAHL. The residues of PDZ2 $\alpha$  that experience a resonance shift larger than  $\Delta\delta_{avg} > 250$  Hz upon addition of Ac-AQPPAHL are marked with a red asterisk. The residues that observe a resonance shift of  $175 \text{ Hz} < \Delta\delta_{avg} < 250$  Hz bear a yellow asterisk; **B.** Mapping of the effect of Ac-AQPPAHL on PDZ2 $\alpha$ . The color coding is the same as in A. The C $\alpha$  atoms of relevant residues are represented by a sphere while the side chains are shown as sticks. The last four residues of peptide (PAHL) were modeled in PDZ2 $\alpha$  on the basis of the PSD-95-peptide complex (PDB accession code 1BE9 (Doyle *et al.*, 1996)) and are represented in green. The atoms colored in cyan correspond to the C-terminal carboxylic group

It is observed that the shape of the signals changes during the titration of Ac-AQPPAHL into the PDZ2 $\alpha$  solution. Figure 4.4 shows the decrease of intensity and broadening of the resonances of Gly 47 upon addition of Ac-AQPPAHL. After a ratio peptide:protein of 1:0.6, the signals sharpen up and regain intensity, typical of an increase in the free/bound exchange rate, and a change in the fractions away from 50%/50%. An analysis of these results indicates that the dissociation rate constant is on the order of 1000 s<sup>-1</sup>. This results in a fast exchange regime for nuclei that exhibit small chemical shift perturbation and intermediate to slow exchange for the nuclei with large resonance frequency changes.

Figure 4.4: Cross-section through the <sup>1</sup>H resonance of Gly 47 of PDZ2 $\alpha$  at different titration points with Ac-AQPPAHL. The ratios are indicated at the right hand side of the graph, in equivalents (eq) of Ac-AQPPAHL:PDZ2 $\alpha$ .

## IV.3.3 - Importance of the residues of Ac-AQPPAHL in binding

To establish the relative importance of the individual residues of the Ac-AQPPAHL peptide for binding to PDZ2 $\alpha$ , titrations were performed with several peptide variants.

Interactions of PDZ domains with their C-terminal targets have been reported to involve the last four to six residues of the peptide (Fanning and Anderson, 1999), although interactions down to residue P<sub>8</sub> have also been postulated (Cai *et al.*, 2002; Birrane *et al.*, 2003). P<sub>0</sub> (denoting the C-terminal residue), P<sub>-1</sub>, and P<sub>-3</sub> residues were changed into an alanine, one at a time. Also, the influence of the N- and C-termini of the peptide on the affinity was studied. The binding affinities of PDZ2 $\alpha$  for each peptide were derived from NMR titration experiments as described above. The respective dissociation constants are gathered in Table 4.1.

**Table 4.1:** Summary of the binding constants of PDZ2 $\alpha$  for each studied peptide

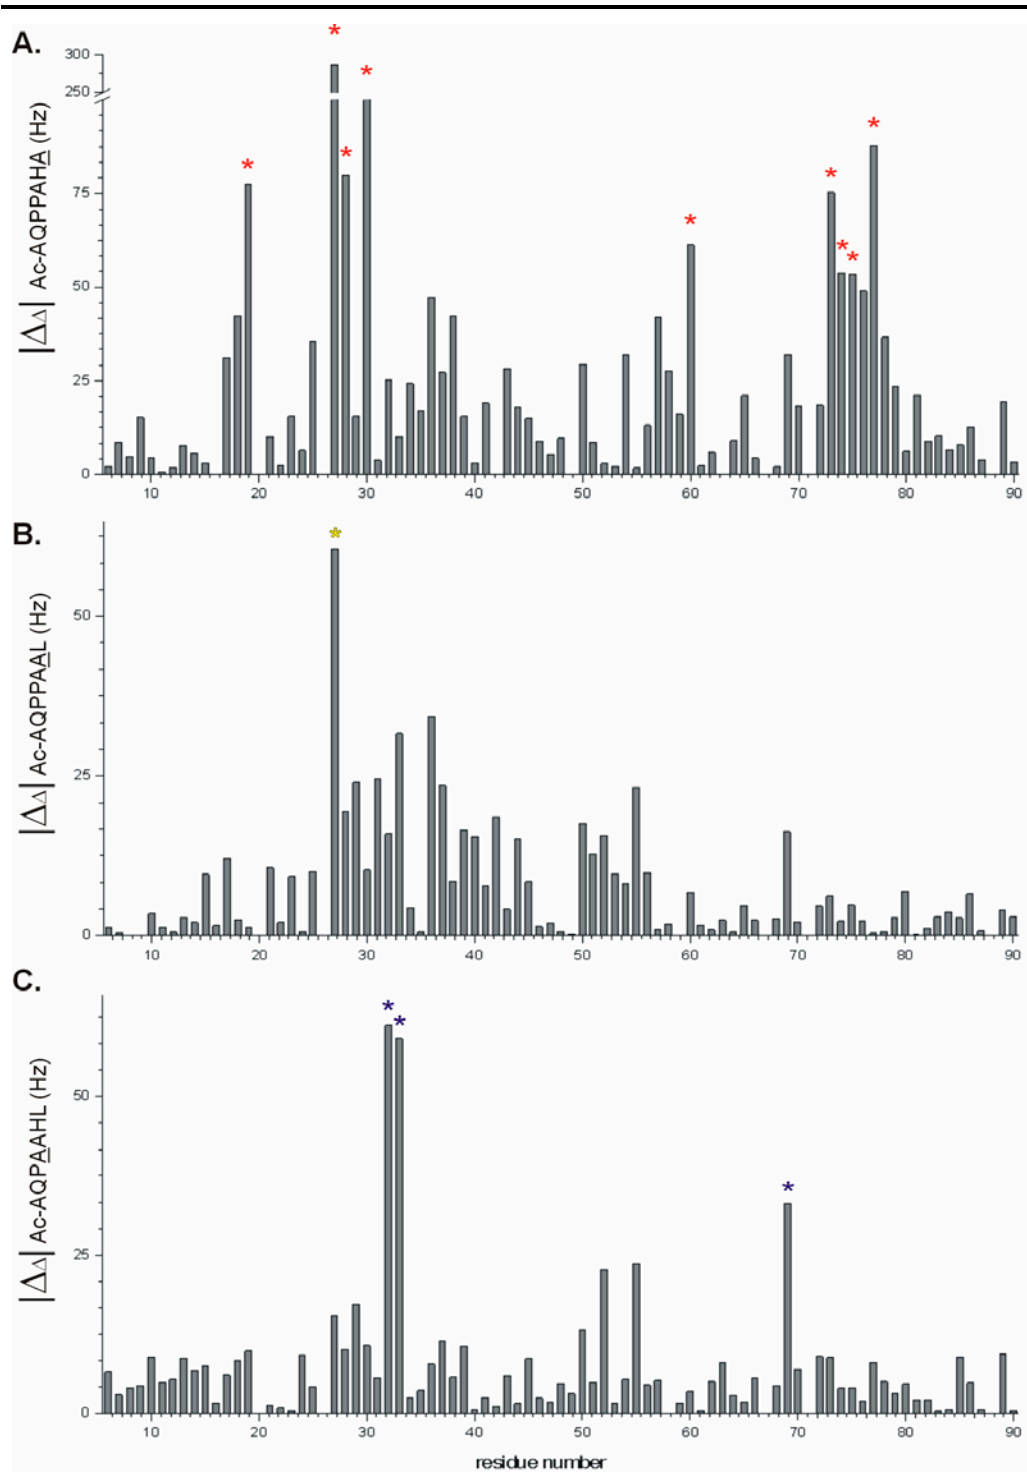

peptide	K <sub>D</sub> ( $\pm$ deviation) in $\mu$ M
Ac-AQPPAHL	91 ( $\pm$ 2)
Ac-AQPPAHL- <u>NH<sub>2</sub></u>	> 55 $\cdot$ 10 <sup>3</sup>
Ac-AQPPA <u>H</u> A	14.3 ( $\pm$ 0.2) $\cdot$ 10 <sup>3</sup>
Ac-AQPPA <u>A</u> L	47 ( $\pm$ 4)
Ac-AQP <u>A</u> AHL	98 ( $\pm$ 2)
<u>A</u> QPPAHL	300 ( $\pm$ 8)

The largest changes in affinity are observed when the C-terminal residue (P<sub>0</sub>) is altered. When the carboxyl-group is neutralized by converting it into an amide group, binding is completely abolished. When the P<sub>0</sub> residue is changed from a leucine to an alanine, the affinity decreases 160-fold. The presence of a positive charge at the P<sub>-6</sub> residue of the peptide decreases the affinity by a factor 3. When the

proline P<sub>3</sub> is changed into an alanine, the affinity remains unchanged. Interestingly, when the P<sub>-1</sub> histidine is changed into an alanine the affinity increases by a factor 2.

The titrations also reveal that a specific peptide variant affects specific residues of the PDZ2 $\alpha$  domain. The absolute difference in chemical shift perturbation ( $|\Delta\delta|$ ) for each PDZ2 $\alpha$  residue was quantified by subtracting its maximum average shift perturbation in the presence of the alanine variant to that of the native peptide (Ac-AQPPAHL). The residues of PDZ2 $\alpha$  that show a different chemical shift perturbation pattern between the native peptide and the P<sub>0</sub> alanine-variant are the conserved Arg 19, Gly 27 and Phe 28 of the binding motif, residue Val 30, and residues His 73, Ile 74, Leu 75, Ser 76 and Asn 77 of the helix  $\alpha$ B (annotated with red asterisks in Figure 4.5A). The only residue that is significantly affected by the P<sub>-1</sub>-variant is Gly 27, although an effect on Leu 26 cannot be ruled out (annotated with a yellow asterisk in Figure 4.5B). Three residues, (Asn 32, Gly 33, and Glu 69, located towards the C-terminal side of  $\beta$ B and the N-terminal side of  $\alpha$ B) sense the change at the P<sub>-3</sub> position (annotated with blue asterisk in Figure 4.5C).

**Figure 4.5:** Histogram representation of the absolute difference of resonance shift ( $|\Delta\Delta|$ ) between the native peptide Ac-AQPPAHL and the alanine variants (the residue that is changed is underlined); **A.**  $|\Delta\Delta|$  with P<sub>0</sub> variant; **B.**  $|\Delta\Delta|$  with P<sub>-1</sub> variant; **C.**  $|\Delta\Delta|$  with P<sub>-3</sub> variant. The most affected residues are annotated with an asterisk.

The residues mentioned above have been mapped the structure of PDZ2 $\alpha$  with the PAHL peptide modeled in (see Figure 4.6).

**Figure 4.6:** Model of the last four residues (PAHL) of CCSIII in the PDZ2 $\alpha$  binding groove. The effects observed upon binding of the P<sub>0</sub>, P<sub>-1</sub> and P<sub>-3</sub>-variants are represented in red, yellow and blue, respectively. The model was obtained by structural alignment of PDZ2 $\alpha$  and PAHL with the third PDZ domain of the synaptic protein PSD-95 bound to its peptide ligand (PDB accession code 1BE9 (Doyle *et al.*, 1996)).

## IV.4 - DISCUSSION

PDZ2 $\alpha$  has an open peptide-binding groove capable of interaction with C-terminal ligands. Titration experiments showed clear evidence that PDZ2 $\alpha$  specifically binds a peptide corresponding to the six C-terminal residues of CCS, with a 91  $\mu$ M dissociation constant.

The loss of affinity resulting from the Leu to Ala mutation of the C-terminal residue or the chemical modification of the terminal carboxy-group clearly indicates that the peptide binds in a canonical fashion between  $\beta$ B strand and  $\alpha$ B helix. We also examined the differential chemical shift effects upon changes of the CCSIII peptide. By quantifying these differences in chemical shift perturbation, it is possible to probe specific interactions between PDZ2 $\alpha$  residues and residues in the peptide. Using the complex of PSD-95 and its ligand (PDB accession code 1BE9 (Doyle *et al.*, 1996)) as a template, we constructed a model of the PDZ2 $\alpha$ -CCSIII peptide complex (see Figure 4.6).

Residues sensitive to the P<sub>0</sub> alanine-variant (see Figure 4.6, shown in red) line the top of the PDZ2 $\alpha$  binding groove and illustrate its importance for binding. The side chain of the P<sub>0</sub> leucine is highly buried inside the binding groove, pointing towards the residues present in helix  $\alpha$ B.

The P<sub>-1</sub>-variant showed a surprising increase in affinity. The chemical shift analysis revealed that Gly 27 (in yellow in Figure 4.6) was the only residue significantly affected by this mutation. The imidazole ring of the histidine P<sub>-1</sub> is oriented toward the Gly 27 residue of PDZ2 $\alpha$ . The increased affinity observed for the P<sub>-1</sub>-variant can be rationalized by the presence of a hydrogen bond between the imidazole ring of the P<sub>-1</sub> histidine and the carboxy-terminal group of the peptide. When the P<sub>-1</sub> histidine is changed into an alanine, this hydrogen bond can no longer be formed, and the carboxylic group becomes more available for binding to the protein. Residues at the P<sub>-1</sub> position have traditionally been classified as unimportant for PDZ-target binding (Doyle *et al.*, 1996). However, more recent reports have illustrated their importance (Kang *et al.*, 2003a; Walma, 2004), suggesting that P<sub>-1</sub> residues potentially provide an essential discriminatory role (Walma, 2004).

The P<sub>2</sub> residue is traditionally a crucial determinant for either class I or class II peptides. It usually is a large hydrophobic residue pointing into the helix  $\alpha$ B. But in the PDZ2 $\alpha$ -CCSIII peptide complex, the P<sub>2</sub> residue is an alanine. Its small hydrophobic side chain is well suited for an orientation inside the apolar interior of the protein, close to the side chain of Val 72. Finally, the P<sub>3</sub> residue is located in the proximity of Asn 32 and Gly 33, at the C-terminus of  $\beta$ B, and Glu 69 at the N-terminus of  $\alpha$ B, but it is not likely to be involved in binding as mutating it does not affect affinity.

CCSIII has been suggested to be a flexible domain, since it is not observed by X-ray diffraction methods in the crystals of CCS (Lamb *et al.*, 2001). This flexibility may well be an essential property of CCS in view of its function in copper transport (see Chapter 1). The crystal structure of the CCS-SOD1 shows that the CCS copper binding domain and that of SOD1 are too far apart for copper transfer. Instead, a mechanism in which transfer is mediated by CCSIII has been proposed (Falconi *et al.*, 1999; Rosenzweig and O'Halloran, 2000). Therefore, the inhibition of CCS activity observed by McLoughlin *et al.* (McLoughlin *et al.*, 2001) could be caused by restriction of the flexibility of CCSIII due to its interaction with PDZ2 $\alpha$ . An alternative explanation might be that X11 $\alpha$  localizes CCS away from its partners and thus prevents it to obtain or donate Cu.

## Chapter V

### Tag removal with Pd(II) compounds

**ABSTRACT**

A new generation of synthetic metalloproteases has recently been developed (by Prof. N. Kostic and collaborators at Iowa State University, USA) using transition metal complexes. These reagents present an alternative for existing proteases with several potential advantages: they are highly specific (for methionine and histidine side chains), they are capable of driving the reaction to completion and they leave the peptidic fragments devoid of any modifications. The efficiency of these compounds, on peptides as well as on whole proteins, has been well established at low pH and high temperature. At neutral pH and mild temperature, however, these compounds have worked on peptides only. The aim of the study presented here was to cleave a fusion protein using Pd compounds and to remove the tag moiety from the protein of interest. Their efficiency was tested here under mild conditions of pH and temperature. These preliminary studies did not show any cleavage activity of the tested Pd compounds under our conditions.

## V.1 - INTRODUCTION

Technological advance and progress in research go hand in hand. For instance, protein purification can nowadays be done in a single step, with the use of specific affinity tags engineered on the protein of interest together with the use of high performance chromatography devices. Helpful as those tags may be during this purification process, they can turn out to interfere with the protein of interest at a later stage of the experimentation. To give an example, crystal growth requires extremely pure protein, for which the purification procedures are often time consuming, hence the use of a tag to speed up the process. But the widely used histidine-tag can be a hindrance for crystal growth. Another widely used tag (the GST-tag) has been shown to alter sometimes the properties of the protein to which it is fused, as in the case of the copper chaperone Cox17 (Srinivasan *et al.*, 1998; Heaton *et al.*, 2001).

Ongoing technical improvements may make the means available by which the tags can be removed after they have served their purposes. Usually, proteases are used after the purification step(s) in order to separate the tag from the protein of interest. Proteases present, however, a number of drawbacks. The first one concerns the specificity of their cutting sites. A particular protease usually only recognizes and cleaves a defined sequence of amino acids specific for that protease. This sequence is engineered between the protein of interest and the tag. However, the same sequence can also be present within the protein of interest resulting in undesired cleavage at this site. Secondly, the action of proteases is rarely brought to completion. After (long) incubation of the tagged protein with a protease, some of the chimerae still remain intact. Thirdly and most importantly, after tag removal, the protein of interest often bears some extra residues derived from the tag. The consequence of the first two drawbacks is the loss of precious material, time and money. The consequence of the third drawback is unwanted modifications on the protein of interest due to the presence of parts of the tag, even after cleavage.

Synthetic metalloproteases have emerged in the past few years as new reagents for protein analysis. Pd(II) compounds have been developed by Prof. N. Kostic and co-

workers (Iowa State University, USA) as a new generation of proteolytic reagents. These new compounds present several advantages. Firstly, they bind specifically to methionine side chains (later on called “the anchor”) (Milovic and Kostic, 2001). Secondly, they drive the reaction to completion. And thirdly, they leave the protein of interest devoid of artificial residues. However these synthetic metalloproteases only work under extreme conditions of pH and temperature, unfavorable for biomacromolecules since they lose their properties. However, Milovic *et al.* have solved the problem by modifying the anchor of the Pd(II) compounds from a Met to a Pro–Met sequence (*vide infra*) (Milovic and Kostic, 2003).

The mechanism of action of Pd(II) has been studied in detail (see Scheme 5.1). The Pd(II) forms a stable six-membered chelate ring with the side chain sulphur of a methionine (the anchor) and the deprotonated amide nitrogen of the same methionine. In this way, the Pd(II) is properly positioned to promote cleavage of the second peptide bond N-terminal from the anchor (the X–Y bond in Scheme 5.1) (Milovic and Kostic, 2002). Two mechanisms of cleavage are possible as depicted in Scheme 5.1:

a) the Pd(II) compound coordinates the backbone oxygen of the second residue N-terminal from the anchor ( $O_x$  in Scheme 5.1), thereby further polarizing the  $C=O_x$  bond and activating the first amide bond N-terminal from the anchor (the  $C-N_y$  bond in Scheme 5.1) for nucleophilic attack by a solvent water molecule.

b) the Pd(II) compound activates one of its water ligands for nucleophilic attack of the X–Y peptide bond.

Polypeptide and protein cleavage with Pd(II) compounds has been demonstrated at pHs between 1.2 and 4.5, validating Pd(II) compounds as tools in analytical biochemistry (Zhu *et al.*, 1998; Qiao *et al.*, 1999). At higher pH however, the protease activity is inhibited because of the formation of stable tri- and tetra-dentate complexes between the Pd(II) compounds and the peptide (or protein) (see Scheme 5.2 **1a-4a**).

**Scheme 5.1:** Two mechanisms of Pd(II) mediated peptide bond cleavage

As mentioned earlier, the low pHs used do not allow to maintain the native properties of many protein of interest. However, Milovic and Kostic have shown in more recent studies that the activity inhibition at higher pH can be overcome when the anchoring methionine is preceded by a proline, leading to improved specificity of cleavage and the possibility to work at neutral pH (Milovic and Kostic, 2003). The mechanism by which this is possible is shown in Scheme 5.2. After formation of the active bidentate complex between the protein and the Pd(II) (complexes **2a** and **2b** in Scheme 5.2), the first and the second backbone nitrogen N-terminal from the anchor can be deprotonated by the Pd(II) and form the inactive tri- and tetra-dentate complex **3a** and **4a**. The pKa of this reaction is lower than 2.3, although the proteolytic activity of the Pd(II) is not inhibited until pH 4.5 is reached. Thus, if the backbone nitrogen of the residue preceding the anchor does not carry any hydrogen, as in the case of tertiary amides, the complex **3a** (and thus **4a**) cannot be formed. Such requirements are met by prolines. By using a Pro–Met sequence, the authors succeeded in cleaving 14-mer peptides with Pd(II) compounds at pHs as high as 7.0. The average occurrence of prolines and methionines is low (5.2% and 2.2% respectively) (Doolittle, 1989). Thus a Pro–Met sequence has a low occurrence in natural proteins. It is thus an interesting target sequence to split chimera proteins

that are obtained through fusion of a protein and a tag, for instance. Such a chimera should possess a Pro-Met sequence engineered between the C-terminus of the protein of interest and the N-terminus of the tag. For this application, a mild pH and temperature of incubation with Pd(II) can be used and the integrity of the protein of interest can be preserved.

The PDZ2 $\alpha$  domain that has been subjected to study in the previous chapters is very stable and well characterized. It is thus a good test-protein to examine the feasibility of Pd(II)-mediated tag removal under neutral pH and mild temperature conditions. For this purpose, a chimera was especially constructed with the free PDZ2 $\alpha$  domain, an engineered Pro-Met sequence and a six-histidine-GST tag.

**Scheme 5.2:** Difference of binding between and X-Gly-Met and a X-Pro-Met

## V.2 - MATERIALS AND METHODS

### V.2.1 - Cloning of the chimera protein

A plasmid containing the PDZ2 $\alpha$ -PM-His<sub>6</sub>-GST was constructed in two steps. First, a plasmid coding for the His<sub>6</sub>-GST tag (pET-tag) was constructed. The GST gene was amplified by PCR from the plasmid pRP265Nb (de Jong *et al.*, 2002) with the following two primers: 5' -TCACCTCGAGATGTCCCCTATACTAGGTTATTGGAAAA-TTAAGGG-3' (coding strand) and 5' -TACAGATCTTATTTTGGAGGATGGTCGCC-3' (non-coding strand). The amplified fragment was digested with XhoI/BglII, and inserted into the XhoI/BamHI sites of a pET3H plasmid (Chen and Hai, 1994).

A plasmid containing the sequence coding for PDZ2 $\alpha$  (residues 745 to 823 of X11 $\alpha$  plus engineered Gly and Asn residues at the N-terminus) was already available in the lab and was used as a template. The PDZ2 $\alpha$  sequence was amplified by PCR using the following set of primers: 5' -GCGAAATTAATACGA-CTCACTATAGGG-3' (coding strand) and 5' -GTGATGCATTGGCGCGGCTGGCA-TTG-3' (non-coding strand). The amplified fragment was digested with XbaI/NsiI and inserted into the XbaI/NsiI sites of the pET-tag plasmid mentioned above, resulting in the final plasmid pET-PDZ-PM-His<sub>6</sub>-GST.

### V.2.2 - Expression and purification

A preculture was prepared in 1.5 ml of rich medium containing 100  $\mu$ g/ml ampicillin, 25  $\mu$ g/ml chloramphenicol, 1% glucose and inoculated with 1  $\mu$ l of a -80°C glycerol stock of *E.coli* BL21 (DE3\*RP transformed with the plasmid pET-PDZ-PM-His<sub>6</sub>-GST) and grown overnight at 28°C. This preculture was used to inoculate 150 ml of fresh rich medium (prepared as mentioned above). Over-expression was induced by addition of 0.5 mM IPTG at OD<sub>600</sub> = 0.7 and the incubation was continued for 3 hours. The cells were then collected by centrifugation, resuspended in 2 ml MilliQ water, and kept at -80°C until the next step. After thawing, the cells were sonicated in the presence of 1 mM PMSF and 0.1% NP-40 (a non-ionic detergent). Sodium phosphate and NaCl were added to the lysate to 10 mM pH 8.0

and 250 mM respectively, followed by centrifugation at 13,000 g for 30 minutes. The supernatant was loaded onto a Ni-NTA resin (Qiagen) saturated with nickel and eluted with a step gradient of imidazole (5, 50, and 200 mM in 10 mM sodium phosphate buffer pH 8.0 250 mM NaCl). The eluted fractions were analyzed on 15% Tris/Tricine/SDS PAGE. Those exhibiting a single band below 40 kDa on the gel were pooled and dialyzed extensively against MilliQ water. Precipitates were removed by centrifugation for 10 minutes at 16,000 g. The protein concentration was determined by UV-spectroscopy at 280 nm ( $\epsilon = 45 \text{ mM}^{-1} \text{ cm}^{-1}$  was estimated using the ProtParam software (available at <http://us.expasy.org/tools/protparam.html>).

### V.2.3 - Palladium compounds

The following two compounds were used:

Pd(en):  $\text{cis-}[\text{Pd}(\text{en})(\text{H}_2\text{O})_2](\text{ClO}_4)_2$ ;  $[\text{Pd}(\text{H}_2\text{O})_4]$ :  $[\text{Pd}(\text{H}_2\text{O})_4](\text{ClO}_4)_2$ , which were generously provided by Prof. Kostic from Iowa State University. A schematic representation of the two compounds is shown in Scheme 5.3.

**Scheme 5.3:** Drawing of the two palladium compounds used in this study

#### V.2.4 - Experimental conditions to test the tag cleavage

Two buffers were used: MES pH 6.0 or HEPES pH 7.0

Non denaturing conditions: vials containing 0.1 M of either buffer, 11  $\mu$ M chimera, 100  $\mu$ M Pd(en) or [Pd(H<sub>2</sub>O)<sub>4</sub>] in a final volume of 100  $\mu$ l were incubated for 24 hours at 4°C, room temperature (RT), or 37°C. Concentrated NaOH was added to correct the pH if needed.

Denaturing conditions: vials containing 5.4 M urea in either buffer, 11  $\mu$ M chimera, 100  $\mu$ M Pd(en) or [Pd(H<sub>2</sub>O)<sub>4</sub>] in a final volume of 100  $\mu$ l, were incubated 24 hours at RT, 37°C, or 60°C. Control experiments were performed in the same buffer and under the same reaction conditions but without Pd(II).

## V.3 - RESULTS

A chimera protein was constructed, consisting of the second PDZ domain of the neuronal adaptor X11 $\alpha$  (PDZ2 $\alpha$ ), a tag made of a Pro-Met sequence followed by six histidines and a GST (see Figure 5.1).

**Figure 5.1:** Primary structure of the chimera. The sequence of PDZ2 $\alpha$  is written in normal font, the histidine moiety of the-tag is underlined, while its GST component is written in italics. The Pro-Met sequence is presented in bold, between the PDZ2 $\alpha$  domain and the tags.

The removal of the tag from PDZ2 $\alpha$  was attempted by means of incubation of the chimera at neutral pH (6 or 7), at temperatures ranging from 4°C up to 60°C, under native or denaturing conditions, and in the presence of one of the two Pd(II) compounds (Pd(en) or [Pd(H<sub>2</sub>O)<sub>4</sub>]).

The palladium compounds were expected to bind the Pro-Met sequence at the methionine, with cleavage occurring at the peptide bond N-terminal from the proline releasing the intact PDZ2 $\alpha$  from the Pro-Met-His<sub>6</sub>-GST moiety of the chimera. In case of cleavage, the band of the chimera is expected to disappear from the SDS-PA gel, and two bands corresponding to PDZ2 $\alpha$  and the tag should appear at 8 and 27 kDa, respectively.

### V.3.1 - Non denaturing conditions

The cleavage of the tag was tested for both Pd(II) compounds in MES buffer pH 6 and HEPES buffer pH 7. After 24 hours of incubation at 4°C, RT, or 37°C, each sample was loaded on a 15% Tris-glycine SDS-PA gel (see Figure 5.2).

**Figure 5.2:** Effect of the Pd(II) compounds on the chimera protein. (1) & (5) whole cells expressing the chimera protein and GST alone respectively; (9) standard molecular mass marker (the masses are indicated at the right hand side of the gel in kDa).

Lanes 1 and 5 show the bands of the intact chimera and of the GST alone, respectively. None of the non-denaturing conditions tested here yield bands at the expected positions (8 and 27 kDa). This indicates that cleavage did not occur. It is conceivable that the arrangement of PDZ2 $\alpha$  and GST with respect to each other

buries the cleavage site, making it unavailable to the Pd(II) compounds. Therefore, similar experiments were performed under denaturing conditions.

### V.3.2 - Denaturing conditions

The same Pd(II) compounds as mentioned above were used in this series of experiments. The denaturing agents are 5.4 M urea (in MES pH 6 or HEPES pH 7) and high temperature. After 24 hours of incubation (with and without Pd(II) compounds) at RT, 37°C or 60°C, the samples were loaded on a 15% Tris-glycine SDS-PA gel (see Figure 5.3A and 5.3B). Figure 5.3 shows that the presence of urea does not promote the cleavage. None of the bands is replaced by two smaller ones at the expected sizes. However, lanes A4 and A6 do present a difference when compared to their controls shown in lanes A3 and A5. The major band is less intense, indicating that some protein has been lost, and appears to run at a slightly higher position on the gels. If the Pd(II) present in these experiments is responsible for that loss, no specific degradation is yet observed. Similar observations are made in lanes A11, A12, B6, B7, B13, and B14 with a less intense band, also indicating loss of material, and at a slightly higher position. However, given that A11, B6 and B13 do not contain any Pd(II) compound, the shift in the band position cannot be attributed to the Pd(II) compounds. The reason for this small shift is unclear.

**Figure 5.3:** Effect of Pd(II) compounds on the chimera under denaturing conditions; **A.** Experiments done with 9 equivalents  $[\text{Pd}(\text{H}_2\text{O})_4]^{2+}$  to the chimera; (13) standard molecular mass marker; (14) purified chimera; **B.** Experiments done with 10 equivalents Pd(en) to the chimera. (1) purified chimera; (8) standard molecular mass marker. The molecular masses are indicated between the two gels in kDa; (-) & (+) indicate the absence and the presence of Pd(II) compound.

## V.4 - DISCUSSION

Pd(II) has been shown in the literature to work well as a specific protease in acidic solutions. The low pH used by Milovic *et al.* however is often not suitable for proteins to maintain their native conformation. In order to preserve their integrity, neutral pH and mild temperature conditions are necessary. Theoretically, Pd(II) compounds should be able to interact and cleave specifically at the sequence Pro–Met. However, the protease activity of Pd(II) compounds under the mild conditions that have been tested here, could not be observed. Several factors may explain the absence of any digestion.

Firstly, there are 12 methionines in the chimera that may compete with the targeted methionine of the Pro–Met sequence.

Secondly, Pd(II) can also bind histidines (Milovic and Kostic, 2001). Although the current pH conditions are too high for cleavage from histidyl anchors, the 16 histidine residues present in the chimera may be possible competitors of the Pro–Met sequence for binding the Pd(II) compounds.

From the X-ray structure of the GST (PDB accession code 1GNE) (Lim *et al.*, 1994) and the NMR structure of PDZ2 $\alpha$  (PDB accession code 1Y7N) (see Chapter 3), only 5 out of the 28 Met/His side chains are buried inside the GST, leaving a total of 23 potential competitors of the targeted Pro–Met sequence. It appears thus that the applied 10:1 ratio of Pd(II) to the chimera may be insufficient. Possibly, the removal of the His-tag (at the DNA level) or its saturation with another metal, or the use of a different tag can shed further light on this problem.

Thirdly, is that Pd(II) compounds are also known to bind and react with urea (Kaminskaia and Kostic, 1998). However, this reaction has only been reported in alcohol and/or acetone. Therefore any interference from urea under the conditions used is not expected.

Finally, our experiments were done in the presence of buffers, while the studies of Milovic *et al.* were done in pure aqueous solutions. The buffers that were used are so called Good's buffers. They are supposed not to react with metal ion, but they may still interfere with the Pd(II) compounds. The same experiments as those presented

here should thus be conducted in the absence of the buffers, with all the precautions regarding the pH of the reaction mixture containing the chimera to be taken into account.

The binding of the Pd(II) compounds on the chimera has also been assumed, but it has not been confirmed. HPLC experiments may shed light on the presence of the possible species of chimera present in the reaction mixture (without Pd(II) and with 1 or several Pd(II) bound), followed by MALDI-TOF analysis on the different fractions to determine the Pd(II) content of each fraction.

Further experiments in this direction are planned.

## **Chapter VI**

**Summary**

**&**

**General discussion**

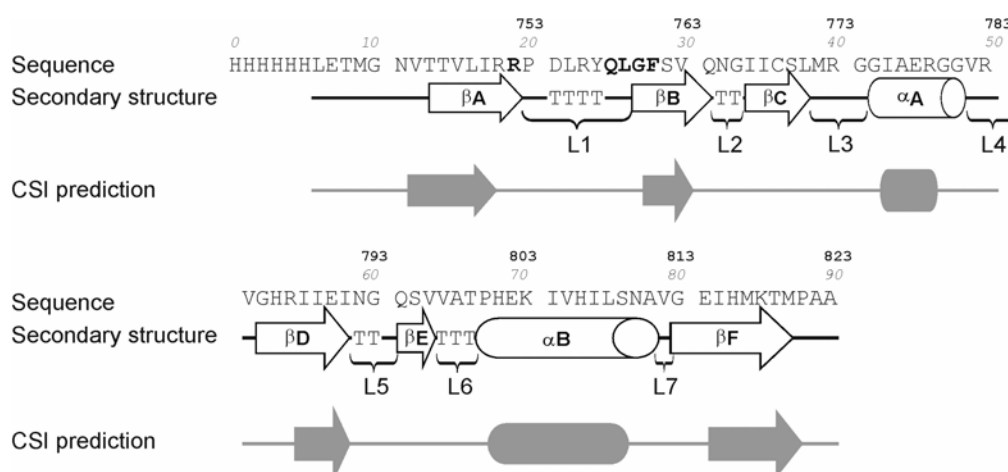

The goals of the research presented in this thesis were to solve the structure of the PDZ2 $\alpha$  domain and to determine the interaction mode with CCSIII. A summary of the results is presented below followed by some concluding remarks.

## VI.1 - STRUCTURE OF PDZ2 $\alpha$

The near-complete assignment of the resonances of PDZ2 $\alpha$  (**Chapter II**) allowed to proceed with the calculation of the structure of PDZ2 $\alpha$  (**Chapter III**). The resulting ensemble of 20 superimposed models shows a well-defined structure. The sequence conservation among different PDZ domains is rather low (see Figure 3.2A). However, the PDZ fold is conserved in PDZ2 $\alpha$ , with six  $\beta$ -strands and two  $\alpha$ -helices which superimpose well onto known PDZ domains, although the CSI prediction performed on the basis of the chemical shifts given in Chapter 2 had indicated only 4  $\beta$ -strands (see Figure 6.1). All actual secondary structure elements are longer than predicted on the basis of the CSI.

**Figure 6.1:** Comparison of the secondary structure of PDZ2 $\alpha$  described in Chapter 3 with the CSI prediction obtained from the chemical shift assignments in Chapter 2.

The structural alignment with the third PDZ domain of Psd-95 (PDB code 1BE9 (Doyle *et al.*, 1996)) and the second PDZ domain of PTP-BL (PDB code 1GM1 (Walma *et al.*, 2002)) revealed two special features of PDZ2 $\alpha$  (see Figures 3.2B), *i.e.* the two loops flanking the  $\beta$ B strand (that holds the consensus binding motif) are

longer and shorter, respectively, than in other reported PDZ structures. However, the conserved residues involved in complex formation are maintained in their positions for ligand binding.

## VI.2 - INTERACTION WITH PEPTIDES OF CCSIII

Probing of the two candidate sequences of CCSIII allowed us to attribute the interaction with PDZ2 $\alpha$  to the last four residues of CCSIII (PAHL) and not to the internal sequence (**Chapter IV**).

The dissociation constant ( $K_D$ ) of PDZ2 $\alpha$  for Ac-AQPPAHL was determined to be  $91 \pm 2 \mu\text{M}$ . This value is in the range of other NMR determined dissociation constants of PDZ-ligand complexes, with values in the low  $\mu\text{M}$  to several hundreds  $\mu\text{M}$  range (Harris *et al.*, 2001; van den Berk *et al.*, 2004). It was concluded that PDZ2 $\alpha$  and Ac-AQPPAHL are in a fast exchange regime, with a  $k_{\text{off}}$  in the order of  $1000 \text{ s}^{-1}$ .

It is interesting to compare the observed chemical shift perturbations of this study with those of other protein complexes. Recently, it has been suggested (Worrall *et al.*, 2001; Worrall *et al.*, 2002) that the perturbation size is an indication of the nature of the complex. In highly dynamic complexes, in which the partners do not assume a single well-defined orientation, the observed perturbations are very small and involve mainly charged residues. Complexes with more defined interactions show larger perturbations upon formation of the complex. Compared to other complexes with such high off-rates, the perturbations observed here are quite large (see Table 6.1), in agreement with a highly specific interaction. It is believed that in particular changes in the water structure on the protein surface, due to burial of surface residues in the interface causes chemical shift changes of amide nuclei. Thus, hydrophobic and polar, uncharged residues usually exhibit the larger changes in well-defined complexes.

**Table 6.1:** Comparison of the characteristics of four transient complexes: cytochrome *c* – plastocyanin (cyt *c* – Pc) (Ubbink and Bendall, 1997), cytochrome *c* – cytochrome *c* peroxidase (cyt *c* – CcP) (Worrall *et al.*, 2001), cytochrome *c* – myoglobin (cyt *c* – Mb) (Worrall *et al.*, 2002), PDZ2 $\alpha$  – CCSIII (Chapter 4).

	Type of complex	Size of $\Delta\delta_{\text{avg}}$	Affected residues	Binding
cyt <i>c</i> – Pc (Ubbink and Bendall, 1997)	dynamic ensemble of orientations	up to 0.02 ppm	mostly acidic	10 $\mu\text{M}$
cyt <i>bs</i> – Mb (Worrall <i>et al.</i> , 2002)	dynamic ensemble of orientations	up to 0.02 ppm	acidic	20 $\mu\text{M}$
cyt <i>c</i> – CcP (Worrall <i>et al.</i> , 2001)	largely single orientation	up to 0.3 ppm	hydrophobic, uncharged polar	5 $\mu\text{M}$
PDZ2 $\alpha$ – CCSIII (Chapter 4)	single orientation	up to 1.2 ppm	hydrophobic	100 $\mu\text{M}$

The study of the alanine variants of the CCSIII C-terminal peptide led to a further characterization of the interaction, and the results are summarized in Table 6.2, highlighting here the change in affinity (compared with Table 4.1).

**Table 6.2:** Summary of the binding constants of PDZ2 $\alpha$  for each studied peptide

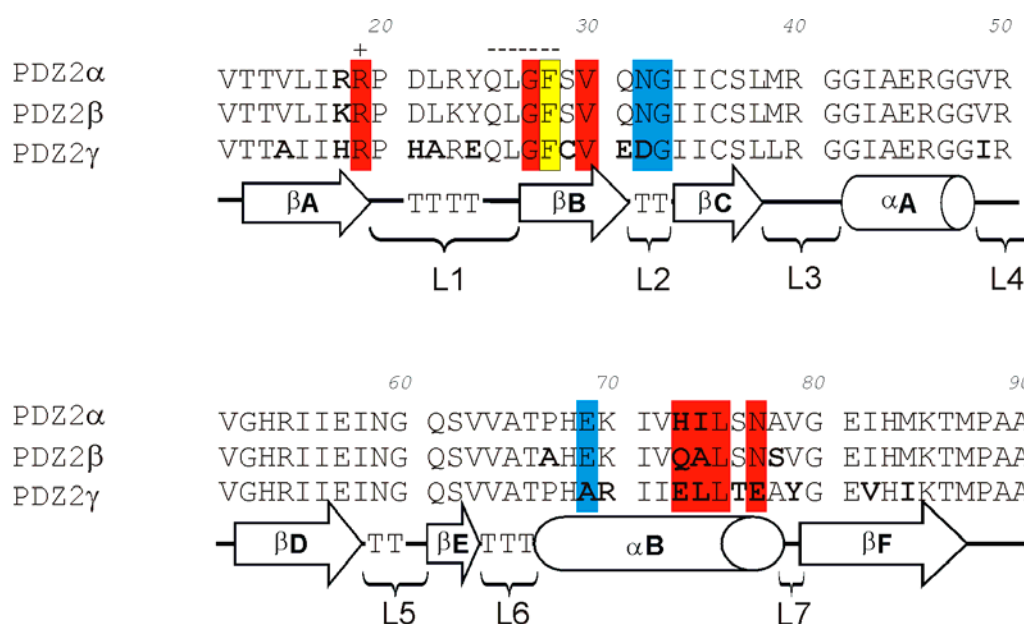

peptide	$K_D$ ( $\mu\text{M}$ )	Change in affinity
Ac-AQPPAHL	91	-
Ac-AQPPA <u>A</u> L	47	$\uparrow$ 2x
Ac-AQPP <u>A</u> AHL	98	no change
<u>A</u> QPPAHL	300	$\downarrow$ 3.3x
Ac-AQPPA <u>H</u> A	14,300	$\downarrow$ 160x
Ac-AQPPAHL- <u>NH<sub>2</sub></u>	> 55,000	$\downarrow$ > 600x
Ac-GLTIWEER-NH <sub>2</sub>	nd	-

These results confirm a canonical mode of interaction between PDZ2 $\alpha$  and CCS. Indeed, the greatest determinant for complex formation is the free carboxyl-terminal group. The results of the alanine variants study suggest that only the last 3 residues of CCSIII interact directly with PDZ2 $\alpha$ , as the P<sub>-3</sub> variant does not affect the binding constant.

It was observed that the P<sub>-1</sub> variant affects only one residue on PDZ2 $\alpha$  (Gly 27) when compared to the “native” peptide. The residues of PDZ2 $\alpha$  that are affected by the P<sub>-3</sub> variant are Asn 32, Gly 33, and Glu 69. It is noteworthy that Gly 27 is situated at the N-terminal side of the  $\beta$ B-strand, and that Asn 32, Gly 33, and Glu 69 are at the C-terminal end of  $\beta$ B and N-terminal end of  $\alpha$ B. Besides, the modeling of the residues PAHL into PDZ2 $\alpha$  suggests that P<sub>-1</sub> is rather surface exposed.

In view of these results, the CCSIII C-terminal peptide can be classified as a P2 type of PDZ ligand, according to the criteria defined by Walma (Walma, 2004).

The sequence alignment of the PDZ2 domain of X11 $\alpha$ ,  $\beta$  and  $\gamma$  (named PDZ2 $\alpha$ ,  $\beta$  and  $\gamma$ , respectively) is shown in Figure 6.2. The colored residues correspond to that of Figure 4.5: the residues of PDZ2 $\alpha$  affected most by the P<sub>0</sub> alanine-variant are highlighted in red, those affected by the P<sub>-1</sub> variant are highlighted in yellow, and those affected by the P<sub>-3</sub> variant are highlighted in blue. The alignment shows that four residues out of the 11 colored in the picture are of a different nature in PDZ2 $\beta$  and  $\gamma$  compared to PDZ2 $\alpha$  (position 32, 69, 73 and 77). The residue at position 74 differs between the three PDZ domains, but it is always a hydrophobic one. As observed in the PDZ2 $\alpha$  structure (see Figure 4.6), the side chains of residues Asn 32, Glu 69, His 73 and Asn 77 are surface exposed, thus unlikely to interact directly with the peptide. Therefore, it can be hypothesized that the nature of these residue is not essential, as long as the backbone is available for interaction. Therefore, we can speculate that the C-terminal end of CCS binds to the second PDZ domain of all X11 family members, enhancing the possible role of X11 protein in copper homeostasis.

**Figure 6.2:** Sequence alignment of the second PDZ domain of X11 $\alpha$ , X11 $\beta$  and X11 $\gamma$  (PDZ2 $\alpha$ , PDZ2 $\beta$  and PDZ2 $\gamma$ , respectively). The residues that differ between the three PDZ2 domains are indicated in bold. The conserved arginine (R19) coordinating the ligand via a water molecule in other PDZ-peptide complexes is indicated with a '+', and the conserved binding motif (Q25 to F28) is indicated with '---'. The residues of PDZ2 $\alpha$  (and their homologues in PDZ2 $\beta$  and PDZ2 $\gamma$ ) interacting with the P<sub>0</sub> residue of the CCSIII peptide are highlighted in red. The one interacting with P<sub>1</sub> is highlighted in yellow. Those interacting with P<sub>3</sub> are highlighted in blue.

As argued in Chapter 1, the flexibility of CCSIII may be essential for copper loading of SOD1 by the chaperone (Lamb *et al.*, 2001). The crystal structure of the yeast CCS–SOD1 complex shows that the copper binding domains of CCS (the N-terminal ATX1-like domain) and SOD1 are too far apart for direct copper transfer. Alternatively, the transfer is proposed to be mediated via CCSIII, as it possesses a potential copper binding motif (Cys–X–Cys) (Falconi *et al.*, 1999; Rosenzweig and O'Halloran, 2000).

The interaction between CCSIII and PDZ2 $\alpha$ , characterized in Chapter 4, and the consequent inhibition of CCS activity observed by McLoughlin *et al.* (McLoughlin *et al.*, 2001) could be caused by restriction of the flexibility of CCSIII upon interaction with PDZ2 $\alpha$ . An alternative explanation might be that, upon binding, X11 $\alpha$  physically keeps CCS away from its partners, thus preventing it from obtaining and/or donating Cu.

## VI.3 - ENZYMATIC PROPERTIES OF PALLADIUM

### COMPOUNDS

Biotechnological research keeps providing scientists with easier, faster and more specific techniques. Prof. N. Kostic (Iowa State University, USA) has developed a series of Pd compounds with protease activities. Under denaturing conditions (low pH and high temperature) Pd compounds are able to bind histidine and methionine side chains, and cleave peptides N-terminal from those residues. There are numerous examples of Pd-mediated cleavage of peptides or proteins in literature (Zhu *et al.*, 1998; Qiao *et al.*, 1999; Milovic and Kostic, 2002). One of the aims is to use them as specific reagents for tag removal of fusion proteins. It was found that a Pro-Met sequence allows Pd compounds to cleave peptides N-terminal from the proline at pH as high as 7 (Milovic and Kostic, 2003). The Pd compounds are thus candidates for removal protocols, as these mild reaction conditions should not alter the biochemical/physical properties of the protein of interest. The work presented in **Chapter V** was aimed at confirming the feasibility of Pd-mediated tag removal under mild conditions. A chimera protein consisting of the PDZ2 $\alpha$  domain (studied in chapter 2, 3 and 4) followed by the Pro-Met sequence and a His<sub>6</sub>-GST tag was used to test the proteolytic properties of two Pd-compounds (Pd(en) and [Pd(H<sub>2</sub>O)<sub>2</sub>]) at pH 6 and 7. No protease activity of the tested Pd compounds could be observed under our conditions. The histidines and methionines represent almost 10% of the total number of residues in the chimera. Although they should not react, they might still compete for binding the Pd compounds.

This study is the first of a series of experiments that may lead to the introduction of Pd compounds as a tool for tag-removal under non-denaturing conditions for the protein of interest.

## Samenvatting

Eiwitten zijn belangrijke macromoleculen van de levende wereld. Gedurende het ontstaan, de groei en uiteindelijk de dood van de levende cel, zorgen eiwitten voor de overdracht van signalen binnenin de cel en tussen cellen onderling. Eiwitten maken ongeveer 15% van de massa van de cel uit, en hun wisselwerking speelt een rol in elk celproces, zoals in de synthese en afbraak van DNA/RNA, in de synthese, vouwing en afbraak van eiwitten, in de signaaloverdracht, in de regulering van de activiteit van eiwitten, en in het immuunsysteem.

Een goed begrip van de wisselwerking tussen eiwitten is daarom essentieel voor het begrijpen van alle processen die zich afspelen in de cel, en uiteindelijk ook voor het ontwikkelen van manieren om verstoorde processen te herstellen.

In de loop van hun synthese verkrijgen bepaalde eiwitten een cofactor, bijvoorbeeld een metaalion. Metalen zijn essentiële componenten van eiwitten die betrokken zijn in metabole processen zoals de ademhaling of fotosynthese. Maar deze metalen kunnen ook giftig zijn voor cellen en daarom bezitten de cellen van elk organisme een systeem dat de metalen verwerkt. Deze systemen zijn specifiek voor elk type metaal en meer of minder complex al naar gelang het organisme.

Een voorbeeld hiervan is te vinden in bakkersgist. Het transportsysteem van koper in dit organisme omvat een membraaneiwit dat het metaal toegang verleend tot het inwendige van de cel (zie Figuur 1.1A). Vervolgens wordt het metaal door een zogenaamd chaperone-eiwit, CCS, getransporteerd naar zijn eindbestemming, in dit geval het eiwit SOD1. Het C-terminale domein van CCS, genaamd CCSIII, speelt een belangrijke rol in het overbrengen van het koperion van CCS naar SOD1.

Onlangs is ontdekt dat CCS ook een wisselwerking kan vertonen met een neuronale eiwit ( $X11\alpha$ ) met als gevolg dat de werking van SOD1 verstoord wordt. Het blijkt dat SOD1 inactief wordt als het PDZ2-domein van  $X11\alpha$  (PDZ2 $\alpha$  in het vervolg) een wisselwerking vertoont met CCSIII.

Het onderzoek zoals gepresenteerd in dit proefschrift heeft als doel het karakteriseren van de interactie tussen CCSIII en PDZ2 $\alpha$ .

Eerst is de structuur (i.e. de driedimensionale vorm) in oplossing bepaald van PDZ2 $\alpha$  met behulp van kernspinresonantie (Nuclear Magnetic Resonance, NMR). Eerst zijn de  $^1\text{H}$ ,  $^{13}\text{C}$  en  $^{15}\text{N}$  NMR spectra toegekend (**Hoofdstuk 2**) en vervolgens zijn deze resonantiegegevens gebruikt voor het bepalen van de structuur van het PDZ2 $\alpha$  domein (**Hoofdstuk 3**). Het ensemble van de 20 beste modellen uit de berekening laat een eenduidig gevormde structuur zien, die alle voor PDZ domeinen gebruikelijke elementen bevat, te weten zes  $\beta$ -sheets en twee  $\alpha$ -helices. Opmerkelijk is dat de uit de resonanties voorspelde structuur duidt op kleinere secundaire structuurelementen en op slechts vier  $\beta$ -sheets. De superpositie van de beste van deze modellen met de structuur van twee andere PDZ domeinen (Psd-95-PDZ3 en PTP-BL-PDZ2) toont twee bijzondere kenmerken van PDZ2 $\alpha$  (Figuur 3.2B): de loop L1 is langer dan in andere PDZ domeinen, terwijl de loop L2 korter blijkt. De bindingsite van het ligand daarentegen, is, zoals verwacht, gelocaliseerd tussen de sheet  $\beta\text{B}$  en de helix  $\alpha\text{B}$ . Het is voorts interessant om te zien dat de tussen de PDZ-domeinen geconserveerde aminozuren, i.e. Gln 25 tot Phe 28, zich bevinden in een positie die gunstig is voor interactie met de liganden, ondanks de grotere lengte van loop L1.

Ten tweede is de interactie tussen PDZ2 $\alpha$  en CCSIII gedetailleerd in kaart gebracht (**Hoofdstuk 4**). Hiertoe is gebruik gemaakt van de gevoeligheid van de chemische verschuiving voor de omgeving van de betrokken kern. Wanneer de ligand gebonden wordt, verandert de chemische omgeving van kernen dicht bij de bindingsplaats, wat leidt tot veranderingen in de NMR spectra. Spectra van PDZ2 $\alpha$  in de afwezigheid en aanwezigheid van verscheidene synthetische peptiden afgeleid van CCSIII zijn onderling vergeleken teneinde te bepalen welke aminozuren van CCSIII wisselwerking vertonen met welke aminozuren van PDZ2 $\alpha$ . Het onderzoek van twee peptiden zoals afgeleid van CCSIII toont aan dat PDZ2 $\alpha$  C-terminale aminozuren van CCS bindt (Ac-AQPPAHL), met een dissociatieconstante ter

grootte van  $91 \pm 2 \mu\text{M}$ , en dat PDZ2 $\alpha$  en Ac-AQPPAHL een snelle uitwisseling vertonen, in de orde van  $1000 \text{ s}^{-1}$ .

Om het relatieve belang van elk residu vast te stellen zijn vijf varianten van Ac-AQPPAHL bestudeerd: Ac-AQPPAHL-NH<sub>2</sub>, waarin de C-terminale carboxygroep geneutraliseerd is, AQPPAHL, waarin de N-terminus van het peptide niet geneutraliseerd is (dus positief geladen) en Ac-AQPPAHA, Ac-AQPPAAL en Ac-AQPAHL, waarin de betrokken residuen vervangen zijn door een alanine. De resultaten van dit onderzoek staan vermeld in Tabel 4.1 en zijn weergegeven in Figuur 4.6.

Allereerst blijkt uit deze resultaten dat de beschikbaarheid van de C-terminale carboxygroep een absolute voorwaarde is voor de interactie tussen PZ2 $\alpha$  en de peptide van CCSIII, omdat Ac-AQPPAHL-NH<sub>2</sub> in het geheel niet bindt aan PDZ2 $\alpha$ . Dit laatste komt waarschijnlijk doordat elektrostatische interactie tussen de carboxy-terminal groep en de zijgroep van Arg 19 niet meer mogelijk is.

Verder is aangetoond dat de belangrijkste residuen van de peptide in de verbinding de leucine en de histidine zijn. De residuen van PDZ2 $\alpha$  die het meest beïnvloed worden door het peptide met de leucinevariant (Ac-AQPPAHA) zijn de hydrofobe residuen van de bindingsholte. Echter, slechts één residu van PDZ2 $\alpha$  (Gly 27 van het geconserveerde bindingsmotief) lijkt beïnvloed te worden door de histidinevariant van het peptide (Ac-AQPPAAL). Het is opmerkelijk dat histidine niet het gunstigste residu is, omdat Ac-AQPPAAL beter bindt aan PDZ2 $\alpha$  dan Ac-AQPPAHL. Dit zou verklaard kunnen worden uit een wellicht aanwezige waterstof binding tussen de histidinezijgroep en de C-terminale carboxygroep van het peptide.

Overigens blijkt de aanwezigheid van een positieve lading op de N-terminus van het peptide slechts een klein effect te hebben op de affiniteit van PDZ2 $\alpha$  voor CCSIII, en de substitutie van het C-terminaal proline residu helemaal geen effect.

Tenslotte is een verkennende studie uitgevoerd naar de mogelijkheid van het gebruik van palladiumbevattende moleculen als zeer specifieke proteasen (**Hoofdstuk 5**). Deze moleculen, ontwikkeld door Professor N. Kostic van Iowa State University USA, vertonen proteaseactiviteit, maar uitsluitend onder pH- en

temperatuursomstandigheden die de eiwitten doen denatureren. Echter, het mechanisme van de reactie suggereert dat de mogelijkheid bestaat om te werken onder mildere omstandigheden indien het palladium bindt aan een Pro-Met sequentie in het te klieven eiwit.

Het doel van het onderzoek was het testen van de proteolytische activiteit van twee palladiumbevattende moleculen,  $\text{cis-[Pd(en)(H}_2\text{O)}_2\text{](ClO}_4\text{)}_2$  en  $[\text{Pd(H}_2\text{O)}_4\text{](ClO}_4\text{)}_2$ , op een chimaer-eiwit dat samengesteld is uit PDZ2 $\alpha$ , een Pro-Met sequentie en een tag (His<sub>6</sub>-GST), teneinde de tag en het PDZ2 $\alpha$  domein te scheiden na zuivering. Onder de toegepaste experimentele omstandigheden is het niet mogelijk gebleken de effectiviteit van de palladiumderivaten aan te tonen. Hiervoor zijn verscheidene mogelijke verklaringen. Het chimaer-eiwit bevat 7% aan aminozuurresiduen die in staat zijn om het palladium te binden. Wellicht dient het experiment herhaald te worden met een groter overmaat aan palladiumderivaten, of met een andere tag.

Dit onderzoek is het eerste in een serie van studies met als doel het ontwikkelen van een nieuwe generatie proteasen die het scheiden van het onderzochte eiwit en zijn tag mogelijk maakt onder niet-denaturerende omstandigheden.

## Résumé

Parmi les macromolécules nécessaires à tout organisme vivant, on trouve les acides nucléiques, les polysaccharides (sucres complexes) et les protéines. Ces dernières représentent environ 15 % de la masse cellulaire. Tout au long de la vie des cellules, ces macromolécules interagissent entre elles et permettent le bon fonctionnement de la cellule. Ainsi les interactions protéine-protéine sont impliquées dans toutes les étapes de la vie cellulaire telles que : la synthèse, la dégradation des acides nucléiques (ADN/ARN), la synthèse, le repliement et la dégradation des protéines, la transmission de signaux (à l'intérieur de la cellule et également entre cellules), la régulation de l'activité des protéines, et la réponse immunitaire. Ces interactions sont finement régulées et une perturbation de ces interactions peut être à l'origine de situations pathologiques.

Comprendre ces interactions est donc d'une importance primordiale si l'on veut comprendre les événements cellulaires, et développer à terme des traitements permettant de corriger les situations pathologiques.

Au cours de leur maturation, certaines protéines acquièrent un cofacteur, tel qu'un métal, indispensable à leur activité. Ces métaux bien qu'essentiels pour de nombreux processus biologiques vitaux (respiration, photosynthèse) peuvent s'avérer toxiques s'ils ne sont pas pris en charge correctement. C'est pourquoi les cellules de chaque organisme disposent d'un système de transport des métaux. Ces systèmes sont spécifiques à chaque métal, et plus ou moins complexes selon l'organisme.

Ainsi chez la levure (*Saccharomyces cerevisiae*), le système de transport du cuivre comporte une protéine membranaire chargée de faire passer le métal à l'intérieur de la cellule (voir Figure 1.1A). Celui-ci est ensuite pris en charge par une protéine dite chaperonne (ici, la CCS), qui l'amène jusqu'à sa destination finale, c'est-à-dire la protéine cible nécessitant ce métal (en l'occurrence la SOD1). Cette protéine chaperonne (CCS) possède un domaine particulier, le domaine III, dont le rôle est prépondérant dans ce mécanisme. Récemment, il a été découvert que la CCS

---

pouvait également interagir avec une autre protéine, la protéine neuronale (X11 $\alpha$ ) avec comme conséquence l'inactivation de SOD1. Cette inactivation résulte de l'interaction entre le domaine PDZ2 de la protéine X11 $\alpha$  (PDZ2 $\alpha$  dans la suite du texte) et le domaine CCSIII (voir Figure 1.1B).

Les travaux de recherche, présentés dans ce manuscrit, décrivent les résultats que nous avons obtenus lors de la caractérisation des interactions entre les domaines CCSIII et PDZ2 $\alpha$ .

Dans un premier temps, nous avons déterminé la structure (*i.e.* la forme tridimensionnelle) du domaine PDZ2 $\alpha$ , en solution, par spectroscopie par résonance magnétique nucléaire (RMN). Tout d'abord nous avons attribué les déplacements chimiques des atomes (H, C et N) du domaine PDZ2 $\alpha$  (**Chapitre II**), qui ont par la suite permis de calculer une structure pour le domaine PDZ2 $\alpha$  (**Chapitre III**). L'ensemble des 20 meilleurs modèles issus du calcul montre que le domaine PDZ2 $\alpha$  possède une structure bien définie, comportant tous les éléments caractéristiques des domaines PDZ. Ainsi PDZ2 $\alpha$  est constitué de six feuillets  $\beta$  et de deux hélices  $\alpha$ . Il est intéressant de noter que la structure prédite uniquement à partir des déplacements chimique indiquait des éléments de structure secondaire de plus petite taille et seulement quatre feuillets  $\beta$ . La comparaison du meilleur de ces modèles avec la structure de deux autres domaine PDZ connus (Psd-95-PDZ3 et PTP-BL-PDZ2) montre que la structure de PDZ2 $\alpha$  est singulière en deux points. En effet celui-ci possède une boucle L1 plus longue et *a contrario* une boucle L2 plus courte. Cependant, il est intéressant de noter que le site de liaison des ligands demeure bien formé, entre le feuillet  $\beta$ B et l'hélice  $\alpha$ B. De même, les résidus acides aminés conservés entre domaines PDZ, *i.e.* Gln 25 à Phe 28, sont maintenus dans une orientation favorable pour interagir avec le(s) ligand(s).

La suite de notre étude a consisté à caractériser les interactions entre PDZ2 $\alpha$  et CCSIII (**Chapitre IV**). Pour cela, nous avons également utilisé la RMN, et la propriété des déplacements chimiques des atomes à varier avec un changement d'environnement. Le principe est que les déplacements chimiques des atomes de

PDZ2 $\alpha$  seront différents selon qu'ils sont ou non en contact avec un ligand. PDZ2 $\alpha$  a donc été observé en absence et en présence de plusieurs peptides synthétiques dérivés de CCSIII. Les spectres RMN ainsi obtenus ont été comparés afin de déterminer quels sont les résidus de CCSIII et de PDZ2 $\alpha$  qui interagissent. L'étude de deux peptides dérivés de CCSIII a montré que PDZ2 $\alpha$  lie les résidus situés en position C-terminale de CCS (Ac-AQPPAHL où Ac- indique que le groupe amino-terminal est protégé par un groupe acétyl) avec une constante de dissociation de l'ordre de  $91 \pm 2 \mu\text{M}$ , et que les deux partenaires sont en échange rapide avec un  $k_{\text{off}}$  de l'ordre de  $1000 \text{ s}^{-1}$ .

Pour établir l'importance relative de chaque résidu, cinq variants de peptide Ac-AQPPAHL ont été étudiés : Ac-AQPPAHL-NH<sub>2</sub> où le groupe carboxy-terminal est neutralisé, AQPPAHL où le groupe N-terminal est déprotégé, Ac-AQPPAHA, Ac-AQPPAAL, et Ac-AQPAAHL où les résidus soulignés et en caractères gras ont été substitués pour une alanine. Les résultats de notre étude (résumés dans le Tableau 4.1 et sur la Figure 4.6) montrent que la présence du groupe carboxy-terminal libre est absolument nécessaire à l'interaction entre PDZ2 $\alpha$  et le peptide de CCS puisque Ac-AQPPAHL-NH<sub>2</sub> est incapable de se lier à PDZ2 $\alpha$ . Ceci est probablement lié au fait que l'interaction électrostatique entre le groupe carboxy-terminal avec la chaîne latérale de Arg 19 *via* une molécule d'eau ne peut plus se faire.

L'étude des autres peptides a montré que les résidus les plus importants dans la liaison sont, par ordre croissant, la leucine puis l'histidine. Les résidus de PDZ2 $\alpha$  les plus touchés par le variant de la leucine (Ac-AQPPAHA) sont les résidus hydrophobes formant la poche de liaison. En revanche, un seul résidu de PDZ2 $\alpha$  (Gly 27 du motif de liaison conservé) semble affecté par le variant de l'histidine (Ac-AQPPAAL).

Il est intéressant de noter que l'histidine n'est pas le résidu le plus favorable dans la mesure où PDZ2 $\alpha$  présente une affinité plus forte pour Ac-AQPPAAL que pour le peptide original. Ceci peut être expliqué par une possible liaison hydrogène entre la chaîne latérale de l'histidine et le groupe carboxy-terminal du peptide, déplaçant ainsi légèrement l'équilibre (voir Figure 4.6).

Enfin, l'absence de protection du groupe N-terminal n'a qu'un effet modéré, et la substitution de la proline C-terminale n'a aucun effet sur l'affinité de PDZ2 $\alpha$  pour le peptide de CCS.

Pour finir, une étude préliminaire sur la possibilité d'utiliser des composés dérivés du palladium entant que protéases de haute spécificité a été menée (**Chapitre V**). Ces composés ont été développés dans le laboratoire du Professeur N. Kostic (université de l'état d'Iowa, USA). Ces composés ont prouvé leur efficacité, mais dans des conditions de pH et de température dénaturantes pour les protéines. Cependant, le mécanisme de clivage par ces composés suggère que ceux-ci pourraient être efficaces dans des conditions douces pour les protéines à condition que ces composés soient ancrés sur un motif Pro–Met de la protéine à cliver.

Cette étude représente donc la première d'une série d'expériences visant au développement d'une génération de nouvelles protéases permettant de séparer une protéine d'intérêt de son ancre peptidique, dans des conditions non dénaturantes, ceci afin de restaurer la protéine native.

Au cours de notre étude nous avons pu tester la capacité protéolytique de deux composés à base de palladiums, le (cis-[Pd(en)(H<sub>2</sub>O)<sub>2</sub>](ClO<sub>4</sub>)<sub>2</sub>) et [Pd(H<sub>2</sub>O)<sub>4</sub>](ClO<sub>4</sub>)<sub>2</sub>) sur une protéine chimère constituée du domaine PDZ2 $\alpha$ , d'une séquence linker Pro–Met, et d'une ancre (His<sub>6</sub>–GST). L'objectif est le clivage sélectif de l'ancre peptidique (Tag) du domaine PDZ2 $\alpha$  après purification. Les conditions testées ici n'ont pas permis de démontrer l'efficacité de ces composés à base de palladium. Plusieurs raisons sont imputables à cela. Tout d'abord, la protéine chimère contient 7 % de résidus capables de lier le palladium. Il faudrait donc répéter ces essais avec un excès plus large de palladium, ou avec l'utilisation d'un autre tag. D'autre part, le milieu tampon peut être un facteur d'échec, et devra donc être optimisé au cours des études ultérieures.

Cette étude est la première d'une série d'expériences visant au développement d'une génération nouvelle de protéases afin de séparer une protéine d'intérêt de son tag, dans des conditions non dénaturantes, permettant l'étude de la protéine en question.

SOD1:	superoxide dismutase 1
TFA:	trifluoroacetic acid

## Acknowledgments

Here we are, at the end of the journey that is a PhD. It's been sometimes a lot of fun, and sometimes long and difficult. Therefore it's been an amazingly enriching experience. And I have been fortunate enough to meet a lot of nice people who have helped in one way or another, who have been supportive and whom I would like to thank dearly.

I will start with my family. They might not be aware of how, but without them I would not have been where I am now. *Omain, 'Pa* : sans vous, il est évident que je n'en serais jamais arrivée où j'en suis, à bien des égards. Je vous suis reconnaissante de tout ce que vous m'avez donné l'occasion de connaître et d'accomplir ; je voudrais profiter de ces quelques lignes pour vous dire de ne pas oublier à quel point vous comptez autant l'un que l'autre pour moi. *Ma* (g.....☺) *Taine*, évidemment un grand merci pour ton aide dans la préparation de ma soutenance ; bon, maintenant que tout ça est fini, j'espère rentrer bientôt, pas trop loin de toi. Je vous aime tous fort.

I also would like to address a few words to the people who have introduced me to Science and research. Cher *Alain*, tu n'es évidemment pas étranger à mon parcours. Je te remercie de m'avoir accueillie dans ton labo et de m'avoir fait découvrir la recherche si jeune. *Hervé, Nan*, merci de votre patience et de votre temps.

*Joséřina, Virgine* de P7: il semble écrit que mes amis les plus proches seront aussi les plus éloignés en distance ! Ma foi, ainsi soit-il! Merci d'être mes amies, mais ne vous éloignez pas trop quand même ☺.

Then I arrived in "the country of the low sky", where I've met an amazing amount of people, so diverse in their cultures and qualities. I'm sorry I'll only name a few here. *Alan, Chico*, I am thankful for your company and friendship; I will never forget the wonderful time we had at Plantage 16, our uncontrollable laughs (often just before Sam entered the kitchen somehow!) and the priceless moments spent together. I wish you weren't so far away physically. *Sharm*, "the girl next door" ☺: thank you for your warm heart and mind, and thank you for introducing me to your world (women magazines and real Asian food! "onder anderen"); it was great to know you were just "a wall away", literally or metaphorically. *Manu*: I am grateful to you for your artistic touch to this book. You have a great mind and great talents so... "Chill out, babe!" ☺. *Gerhild, Virginie*: thank you for making the last few months so fun, it's a pity that we've met only recently.

*Marcellus*: I owe you so much that I cannot even express my gratitude in the right terms; I enjoyed very much interacting with you, whether it was on a professional level or during our French meetings.

During my PhD time, I had the privilege to be working at the Radboud Universiteit in Nijmegen with *Chris, Sander, Hugo* and *Marlies*: I would like to thank you all dearly for your warmth and knowledge sharing and patience with me; *Geerten*, I simply cannot thank you enough!

After a productive day spent at the RUN, I could stay at the Verhoeven Family House. Lieve *Annemiek, Ad* and *Carlijn*: ik wil van harte jullie bedanken voor jullie gezelligheid, steun en vriendschap. Ik vond het heerlijk om bij jullie te zijn.

I also would like to thank dearly my paranimfs *Rob* and *Taine*: thank you for seating next to me, supporting me during the ceremony and just making this day a lot easier.

*Michiel*: you've been there everyday for a large part of my PhD. To you, I just want to say this: tout seul c'est bien, à deux c'est mieux.

Finally, to all my friends: as I wrote in French above, my closest friends seem to end up being the farthest in distance for some reason. Well, c'est la vie! Thank you all for being my friends, but please don't go too far!

## Curriculum Vitae

Aude Duquesne was born on the 22<sup>nd</sup> of May 1977 in Coulommiers, France. She meets science and research at the age of 16, in the group of Prof. L. Sedel. After graduating from the local high school, Lycee Jules Ferry, at the age of 17, she moves to Paris to study biology at University Paris 7. There, she became aware of her attraction for contacts with people from international origins. During her 4<sup>th</sup> year, she went to Leiden for a six months training within the Erasmus exchange programme in Prof. Dr. G.W. Canters, under the supervision of Dr. M. Ubbink and worked on the "development of a covalent paramagnetic probe for NMR studies". Then she went back to Paris for one year to finish her degree and spend one year in the lab of Prof. Dr. J. Josefonwicz, purifying and characterizing the  $\alpha$ -L-fucosidase from scallops. After her graduation in 1999, she had the opportunity to go back to Leiden, for her PhD in the Metallo-Protein group of Prof. Dr. G.W. Canters. There, she has studied the interaction Parts of this thesis were presented orally during the Dutch annual Protein Research Meeting (Studiegroep Eiwitonderzoek, Lunteren, The Netherlands, 2004).
